Abstract: Markets with a strong aesthetic component need constant innovation in concept generation and materials. The development of these materials is extremely dependent on a technological support that could be complemented with monitoring systems. This study presents the development of in-situ monitoring system used in the manufacturing of a natural fiber composite basin using RTM technology. The sensing technology selected for this work was the optical fiber Bragg Grating (FBG) sensors due to advantage such as, electromagnetic interference immunity, small size, good corrosion resistance, ultimate long-term reliability, direct absolute measurement, low cost, embedding possibility and unique wavelength-multiplexing capability.

FBG sensors and a thermocouple selected for this application are meant to take measurements of longitudinal strain and temperature. Two physical parameters that occur in the resin flow and cure crucial for understanding this process.

The aim of this study is to detect the resin flow front in-situ and in real-time in the RTM process.

The FBG sensors are sensible to temperature variation through thermal expansion, making it very difficult to disassociate this phenomenon from the strain caused by the resin flow front.

The use of these sensors allowed to detect the complete filling of the mould and determine the exothermic peak.

7 **1. INTRODUCTION**  
8  
9

10  
11 The present work describes the phases of a prototype development to obtain a  
12 sanitary wash basin in coconut random mat with epoxy resin. The geometry was  
13 highly complex with 12mm uniform thickness walls with cylindrical and symmetric  
14 curvatures, an external geometry without bubbles and local resin concentration. For  
15 these reasons RTM light was chosen as the most suitable production technique.  
16 However the random fiber was too porous and the composite production techniques  
17 concepts must be adapted for this fiber hence great care should be taken for proper  
18 injection strategy. The mould and males were studied and designed considering all  
19 factors. FBG sensors and a thermocouple were placed to monitor the strain and  
20 temperature in loco and real time to understand the behavior of resin flow front [1-4].  
21 The results obtained in the product development will facilitate the optimization  
22 technology production for faster implementation in industrial lines.

50  
51  
52

53 The dimensions of the wash basin were 430mm diameter, 120mm high and 12mm  
54 thick. The materials used for the prototype were random mat coconut fiber with  
55  
56  
57  
58  
59  
60  
61  
62  
63

65

1  
2  
3  
4 1482g/m<sup>2</sup> (98.9 kg/m<sup>3</sup> density) and 15mm thick. The selected matrix was epoxy for its  
5  
6 good resistance to chemicals, low shrinkage and transparency, which confer a  
7  
8 natural color of coconut, and also medium viscosity 600mPa.s that allow a good  
9  
10 injection [5, 6].  
11  
12

13  
14 The moulds and males were studied and designed considering all factors  
15  
16 considered above, and furthermore concerning the fiber porosity, resin viscosity,  
17  
18 demoulding the entire prototype, strategy of injection (inlet and outlet of resin and  
19  
20 vacuum points) and thin wall. The injection strategy was two points of inlet resin, with  
21  
22 a runner on the lower side of the mould to oblige the resin to fill the cavity from the  
23  
24 bottom to the top, and the outlet resin with vacuum in a central point and also in a  
25  
26 upper ring channel with two outlet points.  
27  
28  
29  
30

31 The wash basin model was obtained by machining a high density polyurethane  
32  
33 block and finished with a fine gloss paint coating. Hence the mould was produced in  
34  
35 glass fiber and polyester resin divided in three parts, to allow demoulding from half  
36  
37 sides. Two males were assembly inside the mould, one rigid in polyurethane resin  
38  
39 charged with aluminum powder, and the second flexible in silicone rubber, to allow  
40  
41 demoulding easily the inside part with negative draft (Fig. 1).

## 1. SENSOR BRAGG THEORETICAL CALCULATIONS

A FBG is a periodic modulation of the refractive index of the core of a single mode optical fibre, written by exposure to UV light in the region around 248 nm [7]. This fabrication process is based on the photosensitive mechanism, which is observed in Ge-doped optical fibres [8]. If broadband light is travelling through an optical fibre containing such a periodic structure, its diffractive properties promote that only a very narrow wavelength band is reflected back. The centre wavelength of this band can be represented by the well known the Bragg condition:

$$\lambda_B = 2n_{\text{eff}}\Lambda \quad (1)$$

Where  $\lambda_B$  is the centre wavelength,  $n_{\text{eff}}$  is the effective index of the guided mode and  $\Lambda$  is the period of the index modulation. The FBG resonance wavelength will vary accordingly with temperature or strain changes experienced by the fibre. For a temperature change  $\Delta T$ , the corresponding wavelength shift is given by:

$$\Delta\lambda_B = \lambda_B \left( \frac{1}{\Lambda} \frac{\partial\Lambda}{\partial T} + \frac{1}{n} \frac{\partial n}{\partial T} \right) \Delta T = \lambda_B (\alpha + \xi) \Delta T \quad (2)$$

Where  $\alpha$  is the fibre thermal-expansion coefficient, and  $\xi$  is the fibre thermo-optic coefficient. The wavelength shift, induced by a longitudinal strain variation  $\Delta\lambda_B$  is given by,

Where  $p_e$  is the photoelastic coefficient of the fibre, for a silica fibre, the wavelength-strain and wavelength-temperature sensitivities are  $\sim 13 \text{ pm}/^\circ\text{C}$  and  $\sim 1.15 \text{ pm}/\mu\varepsilon$ , for a Bragg wavelength centred at 1555 nm for standard single mode fibres [9].

## 2.2. MONITORING SYSTEM AND RTM PROCESSING

The facility of multiplexing fiber optic sensors allow one fiber with five gratings, however the complex geometry of the mould might predict problems in positioning the sensor in right places. Hence FBG sensors system planned for monitoring were two groups of two multiplexing optic fibers one with three sensors and the other with one sensor localized strategically in preferential places of resin flow front and in opposite mould side (Fig. 2).

1  
2  
3  
4  
5  
6  
7  
8  
9 The optical fibers were connected to a Braggmeter that records data in real time. A  
10 thermocouple was placed near FBG 2 and connected to a PC with acquisition card.  
11  
12 The sensors were placed inside the mould wall, and the optical fibers and  
13  
14 thermocouple wire were brought to the external, through a hole drilled in the vacuum  
15  
16 seal ring and sealed with an epoxy resin, and then connected to its respective  
17  
18 apparatus.  
19  
20  
21  
22

23 After the application of a liquid release, the preform of coconut mat fiber was  
24 placed inside the mould, following the silicon rubber and the rigid males, and then the  
25  
26 mould was closed with a vacuum pressure of  $0.2 \times 10^5$  Pa through the vacuum seal  
27  
28 ring (see Fig. 3).  
29  
30  
31  
32  
33

34 Due to the complexity of assembling mould, coconut preform and males, when the  
35  
36 close operation was performed, some FBG sensors were submitted to high strains,  
37  
38 resulting in an undesirable broken of them, remaining only three active FBG gratings  
39  
40 and one thermocouple (Fig.4).  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 The epoxy resin was mixed with the hardener and placed in a pressure vessel,  
51 hence the injection started with  $1 \times 10^5$  Pa and the cavity mould under  $0.6 \times 10^5$  Pa of  
52  
53 vacuum. The time of injection was 36min but only at 40min the resin inlet and outlet

3  
4 pipes were closed, so air bubbles in the resin front were allowed to leave out the  
5  
6 mould. The resin start to cure and polymerization occur and after 24 hours the piece  
7  
8 was demoulded (see Fig. 5).  
9

### 10 11 12 13 14 15 16 17 18 19 20 21 22 **3. MONITORING RESULTS** 23 24 25 26 27

28  
29 Since the mould is closed it turns a blind process, questions and doubts arise to  
30 end the injection at the right moment with the cavity saturated with resin and without  
31 bubbles. The FBG sensors and thermocouple were expected to measure variations  
32 when the resin flow front cross them and help to optimize the injection technology.  
33  
34 Although as soon as the mould was closed with vacuum ( $0.2 \times 10^5$  Pa) and also  
35 applied lower vacuum in the cavity ( $0.6 \times 10^5$  Pa) the strain sensors detected  
36 variations. The vacuum seal ring is directly connected to the vacuum pump, without a  
37 pressure control valve, when the vacuum is reduced till  $0.4 \times 10^5$  Pa the vacuum pump  
38 started again to stabilize to the desired vacuum level, originating a higher  
39 compression of the perform and consequently an increasing of the strain in FBG.  
40  
41 This phenomenon can be observed in the graphic results (Fig. 6-8) being the curve  
42

5  
6  
7

8  
9 The injection started at 200s after the reset of sensors system, the sequence of  
10 resin arrival was firstly at FBG2 (930s) after 150s to thermocouple, followed FBG1  
11 (1730s) and finally FBG3 (1790s). The resin firstly arrived at the lateral outlets  
12 (1810s) followed by the central outlet (2160s). The injection end was at 2400s all  
13 pipes were closed just remaining the vacuum seal ring (see Fig.6).

24

25  
26 FBG2 sensor and thermocouple were located nearby however the response was  
27 first detected in FBG2 and only 150s after reach the thermocouple (see Fig. 7). This  
28 is explained by the circular flow front of the resin fill, the measure of FBG sensor is in  
29 the vertical length, of 20mm, and the thermocouple was in just one local point, at  
30 FBG half length (medium velocity of flow front is 3mm/min).

7 **4. DISCUSSION OF RESULTS**  
8  
9

10  
11 RTM light uses a vacuum ring to seal the mould however when FBG sensors are  
12 used to monitor the injection the effect of variations due to vacuum pump are  
13 undesirable as results can lead to misunderstanding. This problem can be avoided  
14 using a rigid close up mould or applying a control valve to maintain vacuum steady.  
15  
16  
17  
18  
19  
20  
21

22  
23 The Analysis of graphic results demonstrates that the resin arrival was detected by  
24 temperature effects instead of strain variations. The differential of temperature  
25 between resin and mould was 1.5°C, measured by the thermocouple.  
26  
27  
28  
29  
30  
31

32  
33 In the end of injection the FBG sensors were submitted to irregular strain  
34 variations due to resin front containing air bubbles originating a turbulent flow which  
35 changes in flow pressure. This behavior allowed observing resin flow front arrival at  
36 FBG1 and FBG3.  
37  
38  
39  
40  
41  
42

43  
44 The possibility of the detection of resin arrival using fiber Bragg Grating sensor has  
45 been understood and validated. These network of optical sensors are helpful to  
46 optimize RTM injection being a guide inside the mould giving data in loco and real  
47 time about resin flow front.

Figure 1 – Schematic of mould, males and prototype.

Figure 2 – Schematic of FBG Sensors Positioning

Figure 3 – (from top to bottom) middle and bottom mould, middle and bottom mould with perform, complete mould before injection.

Figure 4 – Positioning of the remaining 3 sensors (top), Positioning of thermocouple with sensors.

Figure 5 – Coconut fiber wash basin.

Figure 6 – FBG sensors wavelength variation during the monitoring process.

Figure 7 – FBG2 and thermocouple measurements.

Figure 8 – Resin arrival in sensors FBG 1 and 3.
