Roedder, Loken, Kyeongheui and Monga (2006) introduced the model for building concept maps of brands, which is an important approach to measuring brand image from brand association perspective, also offering implications regarding the intensity and uniqueness of brand associations. This model does not offer, instead, techniques to measure the importance of brand associations. This was brought to the original model by authors Schnittka, Sattler and Zenker (2012). They are developing a new methodology called Brand Association Network Value (BANV), which quantifies the overall value of the association network.

Koll and von Wallpach (2013) present the results of two large-scale studies for a product, namely for a service that involves conceptualizing consumer responses. The findings show that a higher degree of association will generate more positive responses from consumers. It also identifies why overlapping associations are not a necessary condition for generating consumer responses. This finding is inconsistent with the managerial practices that attach great importance to the degree of overlapping of brand associations.

In conclusion, the analyzed literature offers a fairly broad spectrum of possibilities to approach brand associations. At the same time, the different dimensions explained do not provide a well-defined conceptual framework, leaving room for future research.

For the research which we will use onwards, we will use the model conceptualized by the authors Roedder, Loken, Kyeongheui and Monga (2006), namely the construction of Brand Concept Maps (BCM), as it provides a structured framework research, it exemplifies and specifies the tools and instructions to follow, and many of the subsequent research is based on this model.

Methodology

Research problem

This research seeks to identify brand associations specific to the Alexandru Ioan Cuza University. Using the identified associations, a conceptual map of representative brand associations for Alexandru Ioan Cuza University will be built for both consumers and non-consumers starting from their individual brand association maps.

Purpose

Designing two conceptual maps of brand associations for consumer and non-brand consumers by synthesizing the maps of individual associations made by each respondent, as well as highlighting the main differences between the two conceptual maps of associations made.

Objectives

O1. Identifying a set of associations created by the Alexandru Ioan Cuza University brand in the minds of the consumers (students of Alexandru Ioan Cuza University) and non-consumers (the students of the four other state universities in Iasi).

O2. Identifying the intensity of the general feeling expressed towards the Alexandru Ioan Cuza University brand, both by consumers and non-consumers.

The research was conducted in two stages:

I. Stage of deduction of associations (elicitation)

II. Stage identifying brand conceptual maps

Tools and methods of research

The first stage was designed to identify a set of major brand association for Alexandru Ioan Cuza University, and then to be used in the second stage of the research. The method used in this step is a qualitative one, having the interview guide as a tool. It was composed of a single open question, ("What associations do I remember when thinking about the Alexandru Ioan Cuza University brand?"), because through this open question the main consumers of the brand - the students, have the possibility to verbalize any associations come to their minds. This stage was intended to provide a wider range of associations, but not just those associations that appear first in the mind of the consumer (also called "top of mind").

The next set of associations of the Alexandru Ioan Cuza University brand was identified at this stage:

Table 1. List of brand associations resulting from the first stage

No.	Associations	Frequency	Representative associations
1	Projects / presentations / teams / suit	24	Projects
2	Exams / grids / backlogs / grades	22	Exams
3	College / FEAA / Law / Geography	20	Colleges
4	Bachelor / Master / PhD	19	Levels of studies
5	Colleagues / friends	19	Colleagues
6	Professors	17	Professors
7	Seminars / courses	17	Courses
8	Students / Studentship	17	Students
9	Reputation / quality / reliability / responsibility / sobriety / popularity / performance	15	Reputation
10	AIESEC / LSE / Asdmark / ELSA / ATRAG / volunteering	14	Student organizations
11	Copou/Copou park	14	Copou
12	Partial / session / evaluation	13	Session
13	Scholarship / budget / fees	13	Scholarship
14	Erasmus / international cooperation / international	13	International
15	History / age / tradition	13	Tradition
16	Home / Emporium / "At the whale" / campus	13	Student campus
17	Library / books / course support	13	Library

No.	Associations	Frequency	Representative associations
18	University / top university / one of the best universities in Romania / the first university in Romania	13	The first university in Romania

As we recorded a wide variety of associations, and most importantly because of this, the occurrence of associations did not satisfy the criterion of 50% of appearances, we used the grouping of associations in lexical fields, as can be seen in the table above (table 1). From each field, we extracted only the most representative associations, as can be seen in the last column of the table.

This research aims to identify both positive and negative associations to make research more complex. The negative associations identified had frequent occurrences much lower than the 50% threshold, however, we have decided to introduce these associations as well. These were selected by the most frequently mentioned criteria (table 2).

Table 2. List of negative associations included in the research

No.	Negative Associations	Frequency
1	Stress	24
2	Sleepless nights	22
3	Boredom	20
4	Headaches	19
5	Anger	19

The second stage was also a qualitative research carried out through 100 personal interviews, using the interview guide as an instrument. At this stage, the respondents were asked to make a conceptual brand map for Alexandru Ioan Cuza University using the associations made available, which we selected in the first stage. To this end, we developed a plan that contains the associations identified in the first stage.

Respondents were asked to select a set of associations they considered as specific to Alexandru Ioan Cuza University. Having an example of a conceptual map of associations, respondents built their map of associations for Alexandru Ioan Cuza University. A mandatory condition in making these maps was to establish links between associations by drawing simple, double or triple lines between them (single lines - weak link, double lines - medium intensity link, triple lines - strong link).

Volume and structure of the population

The volume of the population for the first stage was made up by the students of the Alexandru Ioan Cuza University, especially from the final years or the master, as they are the main consumers of this brand and after 3 or 4 years of study they managed to form a rather clear attitude regarding this brand capable of generating competent and relevant associations. A number of 25 respondents were investigated, as this is considered the optimal and sufficient number for this stage according to the research model identified in the specialty literature.

For the second stage, the population is represented by the students in the Iasi university center, which are registered in the five state universities. The universities were contacted to get the total number of students from each one, as well as their number in terms of gender. These accessible data for 2014 were then processed using the quota sampling method, so we obtained the number of students depending on the gender to be interviewed:

- Alexandru Ioan Cuza University of Iasi: 30 women, 15 men;
- Gheorghe Asachi Technical University of Iasi: 8 women, 20 men;
- Grigore T. Popa University of Medicine and Pharmacy in Iasi: 10 women, 6 men;
- Ion Ionescu de la Brad University of Agricultural Sciences and Veterinary Medicine from Iasi: 4 women, 4 men;
- George Enescu University of Arts in Iasi: 2 women, 1 man.

It can be seen that the sample targeted 54 women and 46 men, which we chose depending on the university. Since the sample consisted of students, their age was between 18 and 27 years of age.

Students from private universities in Iasi are not part of the population of this research, as we can say that they benefit from other types of services, with specifications other than those specific to the public education system.

Research results

In order to achieve the objectives of this research, it is opportune to first and foremost show how we encoded the data obtained during the interview. From each individual association map we extracted the following information:

- The presence of the 23 brand associations.
- The type of lines (single, double, triple) linking to each other or to the brand.
- The level at which the associations were placed (Level 1 - Directly Linked to the Brand, Level 2 - Linked to Level 1 Associations and so on).
- The position of associations (overriding or subordinate).

Calculating the indicators

Using the encoded data, we performed several calculations that are needed in the process of building brand conceptual maps (Bruner & Hensel, 1996, pp.67-83). Thus, we have calculated the following indicators for both consumers and non-consumers:

- A. The frequency of mentioning brand associations represents wherever an association appears in the respondents' maps. For example, "Session" is the association most commonly mentioned by brand consumers. The relative frequency is the percentage value of the frequency of the brand association.
- B. The number of interconnections represents how many times an association is connected with other brand associations. In the specialty literature, interconnectivity is presented as an important element in assessing the degree of centrality of a component within the general association system. For example, the highest value of this indicator belongs to the "session" association. Frequently mentioned associations that have a high number of

interconnections are those that will be considered primarily when selecting base brand associations.

The next three indicators are needed to determine the level at which the associations will be placed within the conceptual maps, directly related to the brand or indirectly.

- C. The frequency of mentioning first-level associations represents how many times associations have been placed on individual maps that are directly related to the brand.
- D. The first-level association report is the percentage ratio between the frequency of the first-level associations and the frequency of the associations.
- E. The type of interconnection indicates how often associations are placed over (overdrive) or under (subordinate) other associations within individual maps. For example, brand consumers not only frequently referred to the association of "projects", but they also placed it most often over the other associations (in the case of 14 individual maps).

The brand conceptual mapping procedure

In designing conceptual brand maps for consumers and non-consumers of Alexandru Ioan Cuza University we followed a five-step process that respects the recommendations of the research model identified in the specialty literature. In table 3, we briefly outlined the main aspects of the two conceptual brand maps.

Table 3. Rules for compiling brand conceptual maps

Steps	Indicators	Rules
1. Selecting core brand associations	The frequency of mentioning associations	The inclusion of associations that have been referenced in at least 50% of the individual maps.
	The number of interconnections	The inclusion of associations that have been mentioned in at least 40% - 49% of the individual maps, if the maximum plus the minimum divided by two of the indicator minus the number of interconnections is equal to or higher than the one of the key associations previously selected.
2. Selection of first level associations	The frequency of mentioning first level associations	The ratio of the frequency of mentioning the associations of the first level to the frequency of mentioning associations - at least 50%.
	The ratio of the frequency of mentioning the associations of the first level to the frequency of mentioning the associations	
	The type of interconnections	The inclusion of multiple overdrive interconnections as opposed to subordinate ones.

Steps	Indicators	Rules
3. Selection of lines for basic associations	The frequency of links between associations	Identification of the inflection point represents the equality between the number of different bindings and the frequency of occurrence of the links. The inclusion of links between associations that match or are larger than the inflection point.
4. Selection of lines for secondary brand associations	The frequency of links between associations	The inclusion of associations that are related to the basic ones, respecting the condition of the inflection point mentioned in the previous step.
5. Selection of line types (single, double, triple)	The average number of lines per link	Determination of the average number of lines for each link used in the previous steps, which will be rounded to the nearest whole number.

Thus, following the guidelines in the table above, we will continue to present the conceptual brand maps obtained for both consumers and non-consumers. The first purpose of this research is to build up the maps below (figure 1 and figure 2)

Figure 1. Conceptual brand map for brand consumers - students of Alexandru Ioan Cuza University

Figure 2. Brand conceptual map for non-brand consumers

Considering the second purpose of this research, we have verified the existence of significant differences between the intensity of the general feeling expressed by consumers and non-consumers towards the Alexandru Ioan Cuza University brand. To this end, we analyzed the answers provided by respondents to Section IV of the interview guide, namely the question: "Indicate on a scale from 1 - extremely negative to 10 - extremely positive what are your feelings about Alexandru Ioan University Cuza". The average consumer score was 7.78 ($M = 7.78$) and the non-consumer ratio was 7.44 ($M = 7.44$). It can be said that both the students of Alexandru Ioan Cuza University and the students from the other four state universities in Iasi have on average the same feelings for the Alexandru Ioan Cuza University, the average of 7.78 and 7.44 respectively, denotes positive general feelings towards the brand.

Conclusions

Branding is the science as well as the art of managing consumer brand associations between a brand and public memories about that brand. It can be viewed from the perspective of two extremes, as a set of well-defined components that can be influenced to achieve a certain result, or as a set of confusing and elusive images of the consumer's mind.

The importance of brand associations in the mind of the consumer, therefore, appears to be the key determinant in the long-term relationship of the consumer with the brand. Moreover, the identification and measurement of these associations represent the main objective of the managers in defining the brand communication strategy and the main purpose of this work.

The results of this research have generated two conceptual maps for the Alexandru Ioan Cuza University brand, which were achieved following a five-stage algorithm. We have found that both consumers and non-consumers have in mind the following set of common associations: Copou, Reputation, Students, Professors, Scholarship, Student Organizations, Student Campus, Exams, Projects, Session. While those specific to consumers are: Colleagues, International Cooperation, First Romanian University,

Stress, and Non-Consumers: Library, Courses, Faculties, Tradition, Sleepless nights. One of the causes of the emergence of more common but specific associations could be the availability of these associations for both groups, as it can be seen that they are not related to the specific consumer experience and are rather general, possibly they could be applicable to other academic institutions.

Analyzing the number of links between associations and their type, we have seen relatively higher values for the consumer map than for non-consumers. Thus, although the associations are similar, the relationship between them and their intensity is no longer the same. This increases the intensity of links, due to the multiple experiences of consumers with the brand and the higher degree of familiarity.

During the interview, the respondents were also asked about the intensity of their general expressed sentiment towards Alexandru Ioan Cuza University, being asked to give a score on a scale of 1 to 10 (1 - extremely negative, 10 - extremely positive). The average consumer score was 7.78, and the average of the marks given by non-consumers was 7.44, as it can be seen, there were no significant differences between environments. Both environments suggest positive general feelings towards the brand, which should be appreciated by the management of the institution, but it was also intended to increase this degree in the future.

Finally, assessing the degree of familiarity and previous experience with the non-consumer brand, we noticed that only 11% of the respondents did not visit any of Alexandru Ioan Cuza University's headquarters and 13% did not know or did not meet students/professors / employees of Alexandru Ioan Cuza University.

Intentional or not, it is certain that Alexandru Ioan Cuza University has formed a brand image in the minds of students through a group of closely linked associations.

Useful future investigation directions to be mentioned here would be: simplifying the way data is collected from the interview to the application of an investigation, incorporating into the method the variables that could measure the nature of the links between the associations and could explain the reasons for linking the associations in a certain way, but also testing whether this research can be done through a survey based on an online questionnaire.

Abstract. *This study reports empirical results of a survey on consumer trust in trustless trust facilities provided by distributed ledger technologies, using the example of an app that obtains product-related information from a blockchain. We report results from 82 respondents who were familiarized with the features of the app under consideration. The novelty of this study is that we provide an assessment of consumers' trust regarding the concept of trustless trust. The relevance for practitioners arises from the abundance of quality certifications, eco-labels and product reviews that add confusion rather than orientation to consumer decision processes at the moment of truth (on- or off-line buying decisions) in combination with the increasing popularity of smart contracts, which can be used to store all the relevant information about product details and processing along the supply chain.*

Keywords. *Blockchain; Distributed Ledger Technology; Product Information; Smart Contracts; Trust; Trustless.*

A lie can travel half way around the world while the truth is putting its shoes on.

Introduction

Trust is an underlying determinant that 'participates' in many decisions that managers, employees and consumers make every day. Trust guides both conscious and unconscious choices and can be amplified by digital technologies (Falkenreck & Wagner, 2017). Trust is based on knowledge, using evidence from the past. Contrastingly, faith is based on the complete absence of evidence. The reference to the past explains the power of trust, but also its fragility (Rousseau et al., 1998). When there has been no negative history, no evidence actions, no rumors nor bad experiences, trust is built easily, and people perform more openly. However, such a state of information environment is unlikely (Decker, Scholz & Wagner, 2004; Scholz & Wager, 2006). Worsening the situation, more and more information is produced all over the world, forcing people to cope with a stream of real-time information and huge amounts of data (Ontrup et al., 2009).

Once trust has been broken or even damaged, it is highly difficult, if not impossible, to restore the previous level of trust within same circumstances. Being a powerful motivator, trust is a subject of intense interest to those who need people to make specific decisions. Often information is presented in a subjective way or even misrepresented (Scholz, Meißner & Wagner, 2006). Data manipulation has become a relevant problem

in modern world. For example, a solid proportion of peer-reviewed scientific studies cannot be replicated (Maxwell, Lau & Howard, 2015). The soundness of the information inputted is an important part of the decision-making process and directly influences the quality of the decisions made. The absence of reliable sources of truth and an increasing amount of data require that people spend more time in analyzing the information and making decisions. Unfortunately, time is a limited resource that cannot be produced. In order to make a decision in the same timespan as before, a person needs to handle increased information. People try to involve machines to make calculations and perform tasks involving logical reasoning tasks (Schwerdtfeger & Wagner, 2009).

Herein trust is defined as accepting risk in a relationship when there is no reliable information or limited information at all (Büttner & Göritz, 2008). By sharing trust, it is possible for the parties to any relationship to save resources that would be spent on investigation of information. This point is where blockchain technology enters and unfolds its potential for changing the situation. This technology provides a trust surrogate for the parties participating in the system by freezing information and sharing that frozen information (Glaser, 2017). Therefore, it is attractive in the absence of a single source of truth and a lack of reliable sources of information, particularly in cases when suppliers of products use misleading descriptions of product attributes (Amazon, 2018; Online Shopping Rights, 2018). Incorrect information can be intentionally provided or can be a result of an unintentional mistake. In both cases, consumers are at a disadvantage as they are not informed about the true product attributes. Information can be validated by evaluating labels (tags, packaging, manuals, etc.) or considering reviews provided by buyers or users. However, in both situations, consumers cannot be assured of obtaining reliable information. Particularly in online reviews, important details might be omitted to support individual opinions and experiences.

Disputed ledger technologies have the potential to overcome this shortage of reliable information. However, why and when people trust the information in a blockchain must be clarified for it to advance as a problem-solving technology. Despite the years that have already passed from the initial introduction of this technology and the prominence it gained through the Bitcoin hype, it still appears to be in the beginning stage of its life cycle (Gatteschi et al., 2018). Therefore, this study aims to investigate consumer trust and what people think of blockchain technology by using a prototype of distributed ledger-based tool. This prototype aims increase people's trust by retrieving information from the blockchain with a user-friendly interface and, thus, save consumers resources for better purposes. However, blockchain technology cannot assure the user that the information is correct. What can be assured is that the entries, transactions, and changes are consistent as they are decentralized and immutable. If the initial input was wrong and the correctness of the initial data has not been validated, then all further transactions related to this information are also unreliable (Teacy et al., 2006; Jøsang et al. 2007). For those customers who know what a blockchain is and what features this technology provides, the use of a blockchain should not increase trust as the blockchain itself would serve as a database and not a source of truth. On the other hand, for some customers the wording "blockchain technology" could be a sign of trustworthiness and reliability. The worldwide web is not a completely secure place to store information, an issue which has been demonstrated multiple times as instances of data leaks have become widely known. Blockchain is one of the technologies that are able to increase the level of security of the information on the web and return people's trust in the reliability of Internet-based data storage platforms.

The remainder of the paper is structured as follows: In the next section, we outline our research design and the sampling procedure. Subsequently, we describe the data set and outline the results. In last section, we provide a discussion of results and draw our conclusions.

Research design

In this study, we evaluate a tool that gathers the information about a product into a smart contract and provides this information to the customers. Customers receive only relevant information by applying predefined filters that have been individualized for each customer. The features of the tool are outlined in Figure 1.

Figure 1. Product information flow, including the blockchain and decentralized application.

All the processes of each stage of the supply chain are written into this smart contract (Mik, 2017). In this way, all relevant product information is available for end-users. Some actions, according to the logic of the smart contract, trigger other actions. In this proposal, recognition of the product is realized using a QR code recognition system. This technology is widely used nowadays and is becoming more popular with time (Shin et al., 2012; Okazaki et al., 2018; Yang et al., 2017). This system provides several interfaces where information is inputted externally, but, by the system's design, the entire data flow related to a product happens in an automated manner without human interference. Thus, who has added which information when becomes traceable. However, only with the correct initial input can the advantage of the reliable infrastructure (i.e., the source code and hardware) unfold. This infrastructure allows processing and transferring of the information from one state to another without a loss of data or a breach of integrity. However, the interfaces can be considered as weaknesses because, at the input stages, data integrity depends on the participants.

Taking a user perspective, the application substitutes currently existing formats for presenting product information (tags, eco-labels, online reviews, etc.) with ones enriched with the features inherent in blockchain technology. Notably, combining user personal information with product information provides a unique quality of product feature-related information, reflecting the choices of the individual user at each stage of the supply chain schematically (Martens & Maalej, 2018). Figure 2 reflects the information flow process of the application. Simplification of the user interface will provide a better experience and faster acceptance of the tool.

Figure 2. Schematic representation of the process of user interaction with the product-representing QR code using a personal mobile device.

Consumer and public policy makers are becoming increasingly concerned about environmental issues, especially in food production and the supply chain (North et al., 2003; Zulauf et al., 2013). Studies across the globe have aimed at deriving information about consumer behavior related to healthy and environmentally friendly products (Chan & Lau, 2002; Thøgersen & Zhou, 2012; Pham et al., 2018; Uddin & Khan, 2018). Results support the idea that younger consumers are more concerned about green products and consume healthier food.

Data

Information gathered in a trust-related survey is likely to be influenced by biases. Trust is not a binary variable and, in many cases, trust is a derivative of the interaction of other factors. Nevertheless, various studies demonstrate that the results of a survey highly correlate with the results of experiments (Bellemare & Kroeger, 2007; Sapienza et al., 2013; Naef & Schupp, 2009).

This study builds upon an online survey using Google Forms conducted from May 11-17, 2018. Respondents received a link to a questionnaire and were asked to complete it. They had no time limits and could fill in the questionnaire from any device at any time they wished. In total, 82 people participated in the survey. Fifty-six percent of all respondents were male and 44 percent were female. The age of the respondents varied from 20 to 54 years, while the majority (61 percent) represented the age group 25 to 35 years.

Figure 3. Demographic data of the respondents (gender and age).

Figure 4. Demographic data of the respondents (main occupation and country of residence).

As can be seen from the data concerning occupation, we gathered a sample of mainly working respondents (78 percent). The other 22 percent were spread between study, no current occupation, and other. Respondents lived in Germany, Uzbekistan, Russia, the United States, the United Arab Emirates, Latvia, Italy, France and Cyprus.

Results

The first two questions in the second section of the survey asked about the perception of one's own trustfulness with the question "Can you say that you are a trustful person?" and the respondent's trust in people surrounding him or her, with the question "Can you say that most people around you are trustworthy?" respectively. Only four people responded negatively to both questions. All the respondents who perceived themselves as not trustful and most of the people surrounding them as untrustworthy did not trust information published through social media, newspapers and TV.

Figure 5. Answers to the questions "Can you say that you are a trustful person?" (left) and "Can you say that most people around you are trustworthy?" (right).

Despite the fact that most respondents perceive themselves as trustful and the surrounding environment as trustworthy, most indicated that they would behave cautiously with new products and new people, with 84 percent being cautious with new products and 79 percent with new people. We conclude that people tend not to trust something that is new to them. This finding is highly important for any innovation or novelty and vital for Internet-based commercial activity.

Figure 6. Answers to the questions “Do you agree with the statement ‘When buying a new product (food, clothes, home appliances, etc.), you have to be careful and cautious’” (left) and “Do you agree with the statement ‘When meeting new people, you have to be careful and cautious before trusting them’” (right).

The next set of questions was aimed at testing the extent to which consumers were interested in product description. Consumers products were split into five major groups. Respondents had to measure the frequency of their behavior on a scale from “always” to “never.” As seen from Figure 7, most people cared about information that described foodstuffs. According to the results of the survey, 80 percent of the respondents checked product description at least “sometimes,” which offers motivation to develop a reliable source of information, which will, in turn, be in demand by consumers.

Figure 7. Frequency of product description check, by product groups

Most respondents trust information published in the scientific media or information based on research (Figure 8). Eighty-five percent of all respondents indicated that scientific media were trustworthy sources of information for them. Approximately one third of the respondents trusted official statistics from governmental authorities. Newspapers and TV are still trusted by 45 percent of the respondents, while social media proved to be trustworthy sources of information for 21 percent of the

respondents. Those who did not trust scientific sources of information also did not trust the information coming from other channels.

Figure 8. Trust in information by source

Despite the ubiquitous hype surrounding blockchain technology, 24 percent of the respondents had never heard about this technology. Smart contract technology was known by only 38 percent of all respondents. Approximately one half (53 percent) of those who knew about blockchain technology were aware of both technologies.

Figure 9. Respondents' awareness of about blockchain technology (left) and smart contracts (right)

The results of the survey correspond to the general statistics collected by Google, which are available online via the Google Trends service (Figure 10).

Figure 10. Relative amount of web search requests for 'blockchain technology' (orange line) and 'smart contracts' (blue line) for the past five years. Data source: <https://trends.google.com>

Those who replied affirmatively to the question about awareness of blockchain technology were then asked what the term blockchain technology meant to them and what features belonged to this technology. The highest number of respondents (48 percent) said that a blockchain was a sort of database, namely a decentralized database. The second (46 percent) and the third (37 percent) most popular answers represented a blockchain as a tool for transactions.

Figure 11. Proportion of answers to the question ‘What is a blockchain?’

The fourth most popular answer reported that a blockchain was a “trusted source of information.” Only 21 percent of all respondents considered a blockchain to be a source of information that they could trust. This option was included to see if people would ascribe this attribute to blockchain technology. Because of its design, a blockchain, by default, is not a trusted source of information. Erroneous information can appear and circulate in the system. In defining a blockchain as a trusted source of information and by crediting this feature to blockchain technology, people misunderstand the whole structure and purpose of the technology.

In the next question, respondents were asked to select the features that, to their knowledge, are provided by blockchain technology (Figure 12).

Figure 12. Proportion of answers to the question ‘Which features does blockchain technology provide?’

Notably, 30 percent of the respondents chose “trustworthiness of the stored information” as a feature of a blockchain. It can be assumed that, in general, people expect information to be trustworthy. Only 22 percent of the respondents also said that a blockchain provides them with correct information.

To evaluate the proposition that people value data correctness in digital information storage, the respondents were asked to measure the importance of different features of data storage systems (Figure 13).

Figure 13. Importance of features of digital information storage systems

The top three features with the highest ratings were reliability of the service provider, security of the information and correctness of the stored information. The majority of respondents (84 percent) agreed that it is very important to them to have correct information in a database.

Consumers need an easy-to-use interface for obtaining information without going into the details of the blockchain technology. A set of two questions revealed the proportion of the respondents who used the mobile QR code scanner and how often people used that tool. QR codes are popular nowadays and are used for multiple reasons (Soon, 2008). For example, in many Asian countries, such as China, Japan, Korea, and Singapore, QR codes are integrated in digital payment systems and online banking. Approximately two thirds of the respondents have such an application on their mobile devices (Figure 14).

Figure 14. Proportion of respondents who have a QR code scanner on their mobile device (left) and the frequency of use of the QR code scanner (right).

Conclusion

The concept of trustless trust can seem credible using arguments that appeal to technology; however, it needs to be trusted by consumers. This study provides empirical evidence assessing consumers' trust in trustless trust. Notably, trust is perceived differently by people from different cultural groups. Considering the supply chains of consumer goods, particularly fashion or food items, consumers trust is affected by a dominance of unreliable information. A plethora of quality, environmental and working conditions-related labels adds confusion rather than orientation in a situation where a consumer has to choose. Considering this context, an important first result of this study is the finding that consumers report a need for information they can trust. Four out of five respondents reported that they are cautious when dealing with unknown products and persons with whom they are unfamiliar.

Blockchain technology is proposed to be a possible solution to increase trust and decrease the amount of resources spent on monitoring, control, investigations, etc. Blockchain technology enriches a database with features like immutability, integrity, and consistency, thus making the database more reliable and increasing trust in the data contained therein.

The listed features of blockchain technology are known by the specific people who deal with the data storing processes and the technology itself, but, on average, people are not familiar with the technology and especially with the features provided by the technology. Moreover, when it comes to a further development of the blockchain, namely smart contracts, even fewer people are familiar with this technology and know what it means.

For those who are aware of the existence of blockchain technology, the technology is not expected to ensure trustworthy information. The majority of those who know what blockchain technology is understand that there is no such attribute as trustworthiness and that the data in this type of digital storage system, as a result, lack a trustworthiness component.

At the same time, most of the survey's respondents replied that with regard to information storage systems (i.e., databases), the correctness of the stored data is of the highest importance. Combining these two findings, it can be concluded that a blockchain, despite its unique features, cannot serve as a source of a correct information and that many people understand and agree with this statement. Along with correctness of the information, data security was also very important to the respondents. Recent incidents of data breach have informed people that the Internet is not a safe place to store personal data and that there is a need for other solutions to this problem. A blockchain, according to the results of the survey and also information based on research, can be a solution to the problem of data security. Using cryptography and time stamping while storing the data make it hardly possible with current technologies to undermine protection and perform any sort of malicious act with the data stored in the blockchain. As with any technology, a blockchain has weaknesses; nevertheless, the way data is handled within a blockchain database is more secure compared to other existing data storage solutions.

Abstract. *Studies show that m-commerce markets have different characteristics in different countries. An e-questionnaire survey was used to gather opinions in three groups, totalizing more than 450 Poles, Ukrainians, and Romanians. An analysis was made of the impact of various measures of internet experience on decisions of potential consumers to disclose personal data when downloading paid or free mobile applications. Persons with higher internet experience (measured through length of internet use, length of use of a smartphone and living in a country with a higher e-readiness index) were found to be more likely not to download an attractive app to their smartphone, if a condition of downloading it for free was providing some of their (personal) identification data, in comparison with persons with low internet experience.*

Keywords: *m-commerce; m-application download; privacy; m-commerce in Eastern Europe.*

Introduction

M-commerce, defined as an independent channel for researching and making purchases online with the use of mobile technologies (usually smartphones), is still a new form of buying over the internet, and the value of purchases made this way is far lower than with the use of traditional internet connections. However, due to its dynamic development, m-commerce arouses the interest of both practitioners and researchers. Studies on trust-related barriers in m-commerce are widely conducted (Hew 2017), as not only is the situation in which m-buyers find themselves new, but internet users differ with respect to attitude towards privacy. Qualitative research in the US has recently shown (Hillman & Neustaedter, 2017) that hard (e.g. encryption) and soft (e.g. opinions of other consumers or brand) trust building factors are treated differently by users in the course of mobile purchases (Head & Hassanein, 2002); users are less concerned about the privacy of their data when purchasing in stores with well-known brands.

As buying patterns differ between markets (Zhang, Zhung, & Liu, 2012, p.1902; Akman & Rehan, 2016, p.771), this unexpected result needs to be verified on samples from other countries. A broader range of contextual factors that determine buying-decisions needs also to be analyzed, because readiness to provide information about oneself differs between contexts—as has been shown for e-commerce (Bansal, Zahedi & Gefen, 2016). Our text is a step in this direction. An e-questionnaire was conducted on three different

age groups from three countries—ca. 160 from Poland, 170 from the Ukraine and 130 from Romania. Chosen factors affecting the decision to provide personal data over the internet using mobile devices were analyzed for two situations specific for this kind of commerce: downloading a mobile application, either free of charge or for a payment.

The significance of m-commerce

There are many definitions of e-commerce and the differences between them focus not so much on the scope of using ICT in commercial transactions, as on kind of commercial activity. For instance, in its statistical analyses, Eurostat considers electronic trade to be the sale or purchase of goods or services by different entities—this includes ordering goods or services using computer networks, with on- or off-line payment and delivery, but does not encompass researching information, marketing or image building. One of the UN agencies defines e-commerce more broadly, to also include contact initiation between the potential buyer and seller; exchange of trade information; full cycle of IT care over the client (in this: search, presentation, choice, advice); sale of goods and services, both material and immaterial; financial settlements (every form—including electronic); managing the delivery process to the buyer or the address indicated by the buyer; and post-purchase care. Definitions of m-commerce are analogously differentiated; this, however, is not the only definition-related controversy in the area.

The scientific literature gives us three separate approaches to defining m-commerce (Groß, 2016; Woźniak, 2017; Woźniak & Zbucnea, 2018). Traditionally, m-commerce was defined narrowly as conducting commercial transactions with the use of a mobile device - thus as a part of e-commerce determined by the specifics of the appliance used. As in the case of e-commerce, then, it is possible to distinguish various stages of the commercial transaction and to define m-commerce as the use of a mobile device in any phase of the buying process (Chong, 2013). However, it makes sense not to limit the concept of m-commerce to making purchases using a mobile device, as it has been shown that a characteristic of m-commerce is the high frequency of client activity in preparing for transactions and then following them up (while closure is often done on a different device) (Gross, 2016).

The second type of definition highlights the specific situation created by the use of location-changing mobile devices, which broadens the scope of business models that can be implemented in e-commerce with the use of these devices. Two of the most characteristic new models relate to the possibility of developing services based on users' locations. A common type is commercial offers which sellers assume will be attractive to the user due to their geographical location, e.g. rebate offers directed to people who are near a service point. The second type of business model is based on informing and selling emergency services - such as information about the nearest bus leaving in the direction chosen by the user, or delivery of transport through an Uber-type service. In this case, the user initiates the search for a given service, and his/her physical location determines which potential suppliers that can implement it.

The third group of definitions emphasizes that smartphones have become a personalized media and communications center, permanently linked with the individual. This approach to m-commerce goes beyond the mobility of the appliance and the user's location. It lays stress on the adaptability of the smartphone to the user's individually characterized and specific needs during everyday tasks, and its permanent

presence in the user's life. The result is a highly individualized appliance that serves as a personal communication and entertainment hub (Gross, 2016), with content personalized through mobile apps that can give access to an m-store, or is simply attractive (e.g. sound signals or games). From the perspective of our interests, it is important that a significant proportion of programs that make the user's life more comfortable are downloaded without charge, and that users are aware of the fact that frequently the price they pay for such convenient apps is access to their personal data.

Retaining privacy in m-commerce

Obtaining information about the user (whether it be his location, or for instance the apps s/he has downloaded) gave the e-seller access to some aspects of the client's privacy. In m-business, the information that the user – with his/her specific transaction history – is in a given location, creates a business opportunity, which has a value and can be sold. The more information the m-supplier can obtain about this user, i.e. the more information about the person associated with this concrete appliance is disclosed, the more (a) the services offered may be tailored to the user's needs, but (b) the greater the intrusion into his or her privacy. This tension between benefits and risks for users is sometimes called the personalization-privacy paradox (Lee & Rha, 2016). It is used to show that different categories of users have different strategies for dealing with this situation, depending – among others – on how they perceive risk in given types of situations.

Several earlier studies have shown that trust is a factor which decreases a sense of risk in the m-buying situation (Lee & Rha, 2016). Indicators that inform the user of the e-store's credibility are a standard way in which m-commerce increases the trust of potential users. These may be divided into hard indicators which refer to transaction security (e.g. encryption), and soft indicators (e.g. other users' opinions), including those which give guarantees of privacy (Head & Hassanein, 2002; Hillman & Neustaedter, 2017). M-transaction security is understood as safeguarding the transfer of information against it being intercepted by third parties during interactions. As the m-buyer's physical space cannot be controlled, observation by third parties can go undetected and devices may be unreliable (e.g. batteries fail), such transactions carry a higher level of security risk (Groß, 2016). Privacy concerns relate to the control the user has over how this information is used—while it is being collected, and when it is stored and shared with others. It is understandable that both factors (concerns about security and privacy) are important barriers standing in the way of e- and m-buyers implementing transactions.

The m-trade market in Poland, Romania, and Ukraine

The patterns that m-trade follows have been verified to differ between countries, both as concerns scale, as m-consumer preferences. Specifically, m-trade grows rapidly on markets where – due to low access to traditional line internet access and other infrastructural determinants – e-trade is underdeveloped. For instance, m-trade in India takes second place in the world if one considers the share of m-trade activity in e-trade (over 70% in 2016) (Natarajan, Balasubramanian & Kasilingam, 2017), although most transactions are of a Cash-on-delivery type (Gupta & Arora, 2017, p.2).

Poland, Ukraine, and Romania, which all reformed themselves after the fall of the Soviet Union, are culturally similar to each other. The infrastructure for e-trade is, however, slightly better in Poland than in the other two countries, evidence of which are aggregated indices such as e-readiness, which in 2015 in Poland was higher by over 10%—this gave Poland 42nd place in world rankings. Ukraine took 64th place (upgraded from 75th place in 2012), and Romania 66th. The internet penetration in 2016 were 52% for Ukraine, 60% for Romania and 73% for Poland (<https://data.worldbank.org/indicator/IT.NET.USER.ZS>). The total value of e-trade turnover in 2016 was 8,1 billion Euros in Poland (with forecast 9,4 for 2017), and 1,17 billion Euros in Ukraine (with forecast 1,52 for 2017) and 2,05 billion Euro for Romania (with forecast 2,5 billion for 2017) (EuroCommerce, 2017). Individual purchases valued in euro are also higher in Poland (775 Euro) or Romania (784 Euro in 2015 per online buyer) in comparison with Ukraine (286 Euro). It should be remembered, however, that GDP per capita is far lower in Ukraine (c. 1,800 Euros per capita in 2016) than in Poland (c.11,400 euro) or Romania (c.8,8 000 Euro) (EuroCommerce, 2017).

Differences in levels of m-commerce development seem smaller than with respect to e-commerce as a whole. Data from the Central State Statistical Office for Poland, based on representative samples, shows that for ca.1/3 users, the smartphone is their tool for accessing the internet. 17% users finalized m-transactions in the last 3 months using a smartphone, while 41%—for some part of the e-shopping process. 25% buyers declare that they m-pay regularly, 49% declare they do this from time to time and 39%—regularly. Fairly common also is the use of several tools for accessing the internet (44% use a smartphone, 16% a tablet, 54% a laptop and 36% a desktop computer). 61% buyers declare that they commence e-transactions using a smartphone and finalize them using a different appliance.

For Ukraine, in November 2015, 34% internet users declared that they make e-purchases via a smartphone, and access to 3G data transfer was launched in February 2015 (Pachkovskyy & Maksymenko, 2016). In 2015 PayPal has done some research on the European mobile commerce, interviewed more than 17,500 consumers across 22 countries. It was found out that one in three online shoppers surveyed uses a smartphone to buy online. But this incidence varies significantly by country, and in Ukraine, 57% of respondents declared they have bought something by smartphone in the last 12 months, compared with 34% in Romania and 24% in Poland (<https://ecommercenews.eu/current-mobile-commerce-situation-europe/>).

Over the past few years, m-commerce has been on the rise in Romania (Zbucea, Vătămănescu & Pînzaru, 2015), and data shows Romania to be among the leading countries in terms of purchasing a product/service via mobiles. In March 2016, 42% Romanians stated that they have purchased online using mobiles, compared with the global average of 38% (Nielsen, 2016, p.6). Ukraine took next place, with 41%. In 2017 the figures were even higher, considering that mobile internet penetration was 85% for Romania, and mobile device traffic increased from 50% to 70% (Popescu, 2018). Studies show that online shops still need optimization for mobile, as mobile app conversion rates are higher than in the case of desktop websites.

Methodology of research

The goal of the study is to verify whether internet experience is a modifier of the strength of barriers to trust in m-commerce. It is understandable that several contextual conditions, such as the value of the sum in question, and hence indirectly, the negative consequences that a breach of trust may bring the buyer, modifies readiness to engage in commercial transactions. Readiness to disclose personal information should, therefore, depend on the sensitivity level of this information (Roghanizad & Neufeld, 2015), consistently with the Theory of Perceived Risk (Gross, 2016). The research question concerns the extent to which broad contexts (defined as the exchange of gifts or a purchase) and situational contexts (defined as obtaining an application from a company with a well-known brand or via an encrypted connection) modify this readiness to provide personal data of various kinds.

Readiness to disclose private data has usually been explained through trust in the e-shop, which restricts perceived risk of the negative consequences of one's activity—i.e., one of the two factors that determine a decision based on rational assessment (the other being perceived benefits). Recently, however, an experimental study where data was to be provided in return for a 20\$ coupon gift revealed the limits of this approach—subjects were shown to depend on their emotional evaluation of the seller, rather than to follow a rational model of decision-making (Roghanizad & Neufeld, 2015). The goal of our study is to check if receiving material benefits or the exchange of gifts are factors responsible for readiness to reveal personal data (a possible interpretation of the situation in this experiment). As Marcel Mauss (1925/1990) has stated, the situation in which gifts are exchanged creates a different set of attitudes than the context of buying and selling—it favors an attitude of reciprocating favors rather than maximizing benefits for oneself in the transaction.

The second aspect of our approach is that we focus on the exchange of apps which develop the smartphone's functions as a personal center for management, communication, and entertainment, and which are free. As has been shown, this segment of the m-market is based on creating a potential client of the user of the given application, and so income from providing the user with the app does not dominate in the sellers' business model. Users, however, are accustomed to the fact that obtaining an attractive application sometimes goes in pair with providing personal data, hence this situation is a good one for analyzing readiness to expose oneself to a threat to one's privacy in exchange for obtaining a gift with an attractive value.

The data we use in this text comes from a study conducted on 3 independent samples gathered using the snowball method. Subjects generally have a higher education (or were in college at the time) and lived in large cities (mainly Warsaw, Bucharest, and Odessa). In this way, we received a group of 158 Poles, 176 Ukrainians, and 126 Romanians, demographically differentiated.

The investigation aims to verify if internet experience, variously defined, significantly modifies readiness to provide personal data in four contexts: defining the situation as a gift or purchase, and being oriented towards security signals (ciphering) or well-known brand (i.e. security and privacy concurrently).

The questionnaire constructed for the study – besides a series of questions concerning the context of e- and m-purchases made – consisted of two groups of 3 questions each, characteristic of two situations: the first an exchange of gifts, the second a purchase with a discount and cafeteria with different types of personal data of different level of privacy treats based on (Roghanizad & Neufeld, 2015). The study used several kinds of internet experience indices, but this text refers to three operationalizations:

- Length of time the respondent owned a smartphone with internet access, as declared in responses to a direct question (in 2 groups: “4 years and over” as a long period, and “less than 4 years” as short).
- Respondents were classified as internet experienced if they responded “have used the internet for a long time” and as less internet experienced if they responded that they “have used the internet for a long time, but really frequently not for long”; “I use the internet, but not very frequently”; or “I use the internet if I need to, but I don’t feel too comfortable with it”.
- Representing a country with higher levels of technical and social ICT infrastructure was based on the networked readiness index <http://reports.weforum.org/global-information-technology-report-2016/networked-readiness-index/>. Poland takes 42nd place in world rankings, Ukraine – 64th, Romania – 66th, so we can assume that internet experience of people is higher in Poland and similar in the Ukraine and Romania (See Woźniak, 2015, for an explanation of the construction of the index).

Research results and discussion

Analyzing the declared behavior, one observes similarities, but both differences between the 3 countries. Table 1 shows that in a “gift” context the respondents from Poland are the least trustful – in all investigated situations: general website, well-known brand-website, and ciphered connection. The most trustful are, according to their own evaluation, the Romanians. These results are in line with the e-readiness index presented above. And do not correlate with the degree of internet penetration in the 3 countries. Therefore, the infrastructure seems not to be a determinant factor in m-commerce.

Table 1. Distribution of all positive responses together for submitting different types of personal data in the “gift” context – distributions of positive responses (Source: data from the study)

Item/All positive together	Poland		Ukraine		Romania	
Using a smartphone to download an app which you find attractive (chose one answer for each item: definitely yes; yes; rather yes; difficult to say; rather no; no; definitely no)						
I will give my e-mail address to get the attractive app for free	72	45.6%	98	55.7%	96	76.2%
I will give my full internet data– e-mail address and telephone number– to get the app for free	62	39.2%	69	39.2%	59	46.8%
I will give my postal and e-mail address to get the app for free	51	32.3%	63	35.8%	59	46.8%
I will give my credit card number and e-mail address to get the app for free	32	20.3%	60	34.1%	33	26.2%

Item/All positive together	Poland		Ukraine		Romania	
I will give my credit card number and full address data (including ID card number) to get the app for free	33	20.9%	35	19.9%	26	20.6%
I will withdraw from downloading the attractive app if it is necessary to submit any of my personal data	66	41.8%	27	15.3%	91	72.2%
Using a smartphone to download an app which you find attractive <u>from the website of a well-known brand</u> (choose one answer for each item: definitely yes; yes; rather yes; difficult to say; rather no; no; definitely no)						
I will give my e-mail address to get the attractive app for free	75	47.5%	79	44.9%	102	80.9%
I will give my full internet data- e-mail address and telephone number- to get the app for free	61	38.6%	97	55.1%	82	65.1%
I will give my postal and e-mail address to get app for free	53	33.5%	82	46.6%	68	56.7%
I will give my credit card number and e-mail address to get the app for free	33	20.9%	65	36.9%	37	30.3%
I will give my credit card number and full address data (including ID card number) to get the app for free	23	14.6%	36	20.5%	36	29.7%
I will withdraw from downloading the attractive app if it is necessary to submit any of my personal data	61	38.8%	25	14.2%	81	66.4%
Using a smartphone to download an app which you find attractive if you see that the <u>connection is ciphered</u> (chosed one answer for each item definitely yes; yes; rather yes; difficult to say; rather no; no; definitely no)						
I will give my e-mail address to get the attractive app for free	69	43.9%	68	38.6%	103	84.4%
I will give my full internet data- e-mail address and telephone number- to get app for free	60	38.2%	93	52.8%	86	71.7%
I will give my postal and e-mail address to get app for free	47	29.9%	79	44.9%	77	63.6%
I will give my credit card number and e-mail address to get app for free	33	21.1%	59	33.5%	49	40.2%
I will give my credit card number and full address data (including ID card number) to get app for free	28	17.8%	27	15.3%	44	36.1%
I will withdraw from downloading the attractive app if	56	35.7%	30	17%	81	66.9%

Item/All positive together	Poland		Ukraine		Romania	
it is necessary to submit any of my personal data						

Data above documents some differences between the respondents. For the Poles, there is little difference between the declared behavior in the 3 situations (common website, well-known brand website and ciphered connection). For the Ukrainians, both knowing the brand and having a ciphered connection make a difference. For the Romanian respondents, also knowing the brand counts, but especially having a ciphered connection influences the level of trust and disclosure. Results are a bit counter-intuitive. One would expect that brand trust would facilitate disclosure. The fact that the disclosure is not higher in well-known brands for most respondents suggests that brand trust does not necessary correlates with online commerce trust. The Global Survey on Internet Security and Trust (CIGI, 2018) shows that the security of personal data is a very important factor influencing commerce online. 22% of consumers worldwide would not buy online because of this aspect, while 52% are more concerned about security online- primarily because of cyber-criminality. Poland is the only country among the three which is included in the survey – and the figures show that 12% of the respondents are much more concerned, while 33% are somewhat more concerned about online privacy.

As expected, when asked to give the credit card number, or other information associated with the payment, the level of disclosures drops in all cases, with the Poles being, again, the most cautious. The Romanians are the most open to giving this information, especially if the connection is ciphered. Nevertheless, the Romanians are the ones who declared in a large majority that they would stop downloading any app if personal data is required (although also in the large majority they accept providing information such as postal address or mobile number for instance). This suggests that the significance of “personal data” is not the same among the three country groups. Another aspect to be considered is that it is likely that the Romanians are the ones less aware of security risks. Because of this, they react more when the risks are evident when asked explicitly about giving personal information. This aspect, as well the larger degree of disclosure, might be related to low digital literacy.

Digital literacy is related to the ability to use digital technologies, as well as with the knowledge about it, about the security aspects related to them. Therefore, we should see these results against a digital literacy index and other indicators related to it, such as the e-readiness index presented above in the paper. Mobile connectivity index 2017 (GSMA, 2017) shows that Poland has the highest ranking – 72.71 (consumers’ readiness – 86.25). The digital economy and society index, which considers only EU countries, also places Poland ahead of Romania, with a score of 0,43 – ranked 23, while Romania is ranked 28 (last in the EU) (EDPR, 2017). Also, the New Media Literacy index places Poland ahead of Romania, with 55 points versus 38 (OSI, 2018).

When investigating the same aspects in a buying context, we observe similar answers. The interest to buy does not significantly change the behavior, for most respondents. There is more openness to give credit card information but to a small degree. This is, no doubt, related to the understanding that buying online could not be done without disclosing some information.

Item/All positive together	Poland		Ukraine		Romania	
I will give my e-mail address if it is the condition to buy the app	75	47,8%	94	53,4%	101	82,1%
I will give my full internet data- e-mail address and telephone number- if it is the condition to buy the app	66	42%	87	49,4%	88	71,5%
I will give my postal and e-mail address if it is the condition to buy the app	54	34,4%	69	39,2%	79	64,2%
I will give my credit card number and e-mail address if it is the condition to buy the app	30	19,1%	27	15,3%	53	43,1%
I will give my credit card number and full address data (including ID card number) if it is the condition to buy the app	33	21%	20	11,4%	43	34,9%
I will withdraw from downloading the attractive app if it is necessary to submit any of my personal data	59	37,6%	70	39,8%	85	69,1%

The respondents from Poland basically report the same behavior no matter if they want an app for free or if they buy an appealing one. The Romanians are the ones who modify the most their disclosure behavior, according to the buying intention.

Figure 1. Disclosure readiness (data from the study)

Table 3. Distribution of ‘resign from transaction’ responses (“I will withdraw from getting the attractive app, if it is necessary to submit any of my personal data”) together for delivering different types of personal data in “gift” and “buying” contexts – distributions of positive responses in groups of big and small internet and smartphone experience (in percentages) (Source: data from the study)

	Internet experience		Smartphone experience		Generation			
	Long	Shorter	Long	Shorter	Z	Y	X	64+
Using a smartphone to download an app which you find attractive								
Positive	42.9	28.6	53.3	32.5	50.8	35.4	38.5	28.6
Difficult to say	19.8	29.8	14.4	26.0	13.3	26.9	22.9	25.0
Negative	37.3	41.7	32.3	41.5	35.8	37.7	38.5	46.4
Total no. of respondents	373	84	167	289	120	130	179	28

Table 3 highlights that the respondents with the longest internet experience (using the internet frequently for a long time) and the longest smartphone experience (more than 4 years) are also the ones more cautious in giving personal data. Interestingly to observe that the youngest the respondents, the more cautious they are too. These results could be connected with the understanding of risks associated with personal data disclosure. More experience in using the internet and the smartphones leads to increased digital literacy and understanding of risks, both in the case of gift and buying contexts. This is consistent with the Technology Acceptance Model and the Theory of risk perception additions (Gross, 2016).

Conclusions

The study highlights that even in countries with relatively similar backgrounds, there are differences in terms of disclosure of personal data. Besides socio-economic factors, digital literacy seems to be an important influencer of online behavior, both in gift and buying contexts. Young people, as well as persons with higher internet/smartphone experience, living in a country with a higher e-readiness index are more likely not to download an attractive app to their smartphone, if a condition of downloading it was providing some of their personal data, in comparison with persons with low internet/smartphone experience.

More specifically, from the three Eastern European countries investigated, the Romanians declare to be more willing to share information such as email and postal address, telephone number, and even credit card information. Nevertheless, they are the ones who declare in the largest percentage that they would withdraw from any app download if any personal data is asked. The Poles, who are registering the highest e-readiness and digital literacy, are the most cautious with providing sensitive data.

The investigation also shows that the behavior does not vary significantly when considering a “gift” or a “buying” situation. This suggests that the trust framework is more relevant than the motivation to download an app. Downloading from the website of a well-known brand or having a cyphered connection improves a bit the trust aspect for most respondents, especially for Romanians.

The investigation includes some limits. The sample is a convenience one, not being representative. The questionnaire was applied online, which also makes that the profile of the respondents to be one more open and familiar to using the internet and the smartphones. Another aspect to be considered is that the scales proposed do not measure the actual behavior of the respondents, but the declared one. In reality, the decision is taken considering the actual context of download/buying, factors related to the desire/need to download/buy a specific app etc.

Our study highlights the need for qualitative research in order to better understand the consumer and the factor that influence the situations related to m-commerce. Experiments might also be relevant in order to help business better design their strategies and to attract consumers for m-commerce.

Abstract: *Companies are more and more interested in providing a positive user experience (UX). The aim is to offer a smooth and pleasant experience with the application at hand. In the given context, opportunities should be shown how new marketing strategies consider a digital product from the beginning as an integral part of the corporate communication by the user experience purposefully and in the interaction with a mark is designed. The in-depth understanding and focused management of the Customer Experience (CX) and User Experience (UX) will be critical to future market presence. This includes the holistic view of customer experience, user experience and brand experience as inseparably interlinked disciplines. It is of central importance that each of the three "experiences" is largely subconscious and thus the perception, which is triggered in the interaction with digital products, can be specifically influenced.*

Keywords: *brand experience; user experience; consumer experience management; digital marketing; user journey; experience mapping; user persona; digital touchpoints.*

Introduction

The concept of customer experience was first introduced in 1998 by Jow Pine and Jim Gilmore in the context of an article in the "Harvard Business Review" (Gilmore 2009). Based on the recognition that the economic value of experiences over time surpassed those of products or services and by following an well designed customer experience management (CEM) the companies are able to create a holistic positive customer experience. The aim of CEM is to design and elaborate intense emotional bond resulting from all their interactions with the brand during the customer life cycle in order to increase customer satisfaction, loyalty and advocacy. The Customer Experience (CX) includes all interactions that a person can have with a company or brand which often includes awareness, discovery, cultivation, advocacy, purchases and quality service.

CX combines all those disciplines that were often considered separately so far and assessed: brand, advertising, service management, product management and distribution. An equal, coherent and credible at all contact points, brand experience is the main concern of the CEM. Consumers are not looking at a brands as a collection of different, strategically scheduled operations from marketing, sales or advertising. They experienced a brand holistically, mostly unconsciously, and not that differentiated through which point of contact that is addressed. And yet the consumer makes the decision if he likes a brand or not, based on his experiences at the contact points with

the brand as they are used to reinforce or to build the basic premise of the brand (Courage et al., 2009, p.4791).

The traditionally business model follow consumers based on a linear journey of brand purchase – first the consumer became aware of a brand, learned of a desirable quality it had (through advertising), and consciously decided to purchase it. After personally experiencing the benefits for themselves they became loyal buyers. It's most likely that consumers were always more complex than this and with the arrival of digital brand ecosystems along with the insights gained from behavioural economics it is proven that brand builders need to move on to a more accurate model of consumer decision journeys. The concept of shifting from a 'funnel' to a 'cycle' (first discussed by McKinsey) or even a more complex "experience matrix" system that will mapping out what the consumer does through to the interaction, decision and purchase moments makes sense.

Delivering relevant, branded touchpoint experiences becomes a lot more manageable when marketers clearly understand the needs of the people they are delivering those experiences for – and which touchpoints matter most to those people. The problem they currently face is that the technology used to reach audiences across digital touchpoints has tended to obscure any meaningful sense of who they are targeting and why. When brands' use of programmatic is driven primarily by behaviour, it becomes blind to the people they are interacting with – and the experiences those people might desire in relation with brand promise. Instead, marketers find themselves delivering the same experiences across all touchpoints, driven solely by the last action that people took. At a time when they need to be increasingly nuanced and responsive, this is the wrong way to go. When brands base their programmatic targeting on digital segmentation they tend to transform their results, because they focus on creating relevant moments with the people most likely to buy from them (Conner & Sparks, 2005, pp.170-222).

An extensive analysis of these models shows how brand equity and user experience may be understood better if examined in a broader framework that assesses the incremental effect of the brand at each of the various stages of the consumer's experience and choice process and how consumer experience management play a significant role in how determining actions and content (e.g. attributes) are learned and encoded and then retrieved and used in decisions and choice. These information processing effects would influence part-worth evaluation and combination rules, choice set generation and finally the decision rules used in choice. This broader definition extends the aggregate conceptualization inherent in the "additive" brand impact notion of brand equity (i.e. enhanced attractiveness captured in the utility function) to a more comprehensive approach that focuses on the brand's role across the multi-stage, dynamic consumer experience and choice process (Diamantopoulos et al., 2008, p.1203).

This paper (1) initiates an integration of the multiple extant streams of analyzing user experience, brand equity, consumer learning and brand choice, (2) proposes the incorporation of user experience theories into models of brand choice and brand equity, and (3) suggests a possible synthesis of different brand equity and user experience perspectives. The framework incorporates the new realities, such as the rise of store brands and electronic commerce, which will influence the linkage between brand equity, consumer learning, and user experience.

Brand equity in digital world

Digital will become the loyalty backbone. Many key moments of truth for customers are happening online. This means that more and more of consumers, brand perceptions and attitudes will be based on purely digital interactions (in-app, website, wearable tech, etc.). This has made understanding of customers' digital interactions an essential part of any customer experience program. The voices of consumer (VoC) programs without a web presence engage only 2% to 10% of those who interact with their website (Marketing Sherpa). As we move into the future, this trend will continue. We know that mobile is an inherent part of today's digital experience. Global mobile and tablet internet usage just exceeded desktop use for the first time (GS Stat Counter, 2016) and we also see that 82% of consumers turn to mobile to help make a product decision (Google/Ipsos, 2015).

So it's really no longer a question that, these digital moments, across platforms (mobile, tablet, or desktop) are shaping essential KPIs that will ultimately inform the path to purchase. Nowadays a mobile first mindset and consumer experience design matters more than ever before.

Still there is an ongoing debate among practitioners and business academics about whether brands will retain their importance in this digital experience. As we know brands affect consumer decision rules, choice set formation, perceptions, tastes, perceived risk and information costs; we surmise that each is also differentially affected by the changes that result from the digital experience. To understand the effect of the digital experience on these different roles of brands, we need to understand the differences between the digital and conventional communications, sales and distribution channels (Esposito et al., 2010, pp.207-211). Digital (1) changes the cost for companies and brands to communicate with their customers, which includes lowering the costs of providing consumers with product information and providing companies with opportunities to do market research at lower cost – tracking and diagnosis, gaining actionable insights; (2) it changes the costs for customers to communicate with brands and other consumers by lowering consumers' costs of searching for product information and of participating in discussions with other consumers, and by making it easier for consumers to communicate their preferences to brands along with brand experience; (3) it also changes the form of communication between customers and brands by allowing consumers, for example, to interact about the product both with the company and with other product users; and 4) digital enhances transactional efficiencies (e.g. the cost of executing a transaction).

Therefore we can identify several important aspects now on how digital experience differentially affects various roles of brands; (1) reducing perceived risk and building trust – the new digitally driven metric, “Return on Conversation” – brand engage in a meaningful conversation with individuals and communities which evolves over time – if skillfully and patiently managed, may very well convert to commercial value and long term loyalty based on trust; (2) introducing and keeping a product in consumers' consideration set – lowers consumers' costs of searching for product information; (3) help brand experience extends beyond the awareness and acquisition journey to encompass the sales journey, the product/service usage journey (support), and, lastly, the loyalty/advocacy journey; (4) extends past a single touch point. It includes Facebook ads, billboards, online product pages, and customer service reps. – prospects are

learning about your services from friends and co-workers. As a result consumers are better informed about the quality of search goods and the brand actions. Such consumers may no longer require a brand as a guarantee for product quality since they can assess quality before purchasing the product (Ganglbauer et al., 2009, pp.418-421). It is important to understand that digital experience is not about the next seven days. It is not just a game of clicks received during the time an ad is running. Campaigns and conversions can have a value in immediate returns, but must also be evaluated for longevity. It's about creating digital relationships that go beyond a 'Like' or 'Follow'; relationships that consumers will enjoy and find rewarding long after the brand's investment. As a joint study by SAP, Siegel-Gale, and Shift Thinking suggests in accordance with what makes a brand successful in the digital age – that brands not only have to do things differently they also have to think differently. Where traditional brands focus on positioning their brands in the minds of their customers, digital brands focus on positioning their brands in the lives and doings of their customers. Furthermore, they engage customers more as users than as buyers, shifting their investments from pre-purchase promotion and sales to post-purchase renewal and advocacy so the key is to approach prospects not as buyers, but as future users (Patton, 2012, p.56-60).

Traditional advertising is what brand marketers still use to communicate with their audience – especially TV – but seeking ways to connect with target consumers to leverage their goodwill in terms of feedback following experiences and reshaping brand interaction will help build brand credibility.

We identify five ways in which brands can build equity through digital experience:

Amplify the Brand Offer – digital experience can amplify the product offer by providing additional benefits.

Support the Brand Offer – digital setup can support the brand offer making it easier for consumers to make purchase decisions.

Creating a Brand Building Platform – digital brand-building platforms or a mix of digital assets formed in a comprehensive sequence that delivers a complete brand experience can play a central or leading role.

Amplifying a Brand Building Platform – digital setup can be used to make brand-building work more effectively. The aim will be to deliver an authentic and consistent total brand experience that is aligned with the brand's strategy, positioning and purpose.

User experience is customer experience

There no exception that companies expose their customers to complicated sales processes, confusing websites and apps, long waiting times for hotlines, incompetent service, incomprehensible communication and their application to complicated products. CEM aims to turn satisfied customers into loyal customers and loyal customers into enthusiastic brand or product ambassadors. It is obvious that in this context not only hard facts such as sales, usage intensity or the value of the shopping cart count. Rather, indirect effects such as word of mouth and referrals become important indicators of a company's success (Finneran & Zhang, 2003, pp.475-496).

Looking at digital products, the user experience should be considered as integral part of the customer experience. As already described, digital products and digital experience path are one of the key touchpoints where the user interacts or customer experiences a

brand therefore a good user experience is required for a good customer experience (Frokjer et al., 2000, pp.345-352). A good digital user experience must enable the user to easily find his desired information on a website / landing page or in an app as quickly as possible or at least dealing with the intuitive and engaging task that delivers a micro-moment experience with the brand. This consumer expectation of the product and brand experience should be met and possibly surpassed using triggered associations and emotions that will play an important role in brand likeability.

A good customer experience, on the other hand, gives the user the feeling of one pleasant, professional and helpful interaction between him and brand, ultimately leading to a positive overall impression the company. Ideally, CX and UX are exactly matched and have the same equal quality. This smooth user experience could be rapidly destroyed when for example the website is crowded with information, doesn't have an intuitive flow of the content or the e-mail newsletter or the landing page has no relevance to the user (Harper, 2017). Conversely, a company may have an outstanding advertising strategy and brand perception, a competent sales team and one well-designed organizational structure (C-factors) - but as long as the interacting with a user's website, mobile app, software or content (UX factors) does not work smoothly, fails at the overall customer experience. UX is therefore an important component. Both play a crucial role for the image of a brand, for the loyalty of a customer and thus for the success of a company. Errors in each of the mentioned areas lead to a bad experience with the company or the brand (Boehner, 2007; Ganglbauer et al., 2009).

Paul Watzlawick (2016) described the phenomenon of the impossibility of non-communicating: "You cannot not communicate, because every communication (not just with words) is behavioral and doesn't have a counterpart and just as one cannot behave doesn't mean that you cannot not communicate - because each person responds to the content of communication in the context of the relationship between the communicators" (Watzlawick, 2016). This applies to people as well as to products. The way a product is designed is how it "behaves" (e.g. in animations and transitions - the transition between two states of a page or an element of an interface or a sequence of communication content within the context) and with each interaction certain emotions and associations emerge. It tells a story. It is therefore important to design digital products and content such that they specifically has to trigger emotions and associations at the right moment and in the right story context: you must match the sender, who is usually a company or the brand with the expected user experience. In this interaction with the digital products of a company it must be "triggered" the same story like those that it communicates on all its channels (Rae, 2015). The user experience and brand experience must be congruent and to be able to be quickly understood apart from the noise surrounding the user because the rational mind is the purchase driver in most cases even though perception of digital products / communication and the associated triggering of emotions and associations are mostly subconscious and driven by the subconscious thoughts, feelings and passions which drives impulse purchase decisions, that justified "a posteriori" - rationally after being made emotionally.

The goal must be to mentally influence the thinking and decision-making of the consumer and, as a result, to break the deadlock of low involvement. Another objective is to stimulate the consumer at his neural contact points (focal points) and then to substantiate these with emotional values in order to influence decision making and enhancing engagement. Behavioural anchoring for example - states that the first piece

of information your customer receives is highly important and it can be the basis for any subsequent decision making and set the tone for their purchasing behavior. As individuals, we are rarely able to evaluate the value of something based on its intrinsic worth, but instead we feel the need to compare it with the alternative or surrounding options – for example, if a customer are looking at two hotel rooms which are priced similarly but one offers a free coffee in the morning, he is much more likely to go with the free coffee and to explore the quality of the rooms offered or any detailed features. So comparing bundle packages or deals against each other is the way to take advantage of this “anchoring effect” (Patton, 2012, p.86).

Customer experience and user experience as brand experience factor

Successful CX requires knowledge of best practices and a well-considered plan. That plan must be based on an outside-in view of customer wants and needs as defined by your VOC data, customer insight and other research methodologies. It takes tools like personas and journey maps to establish a customer-centric design, and a CX strategy that defines priorities in relation with consumer behaviour, justifies investment and drives cross-functional collaboration (Willis, 2016).

The user experience (UX) considers the use of a user with a (digital) product or band as well as the feelings and associations along with the experience resulting from this interaction. The term is a collective term for different categories of digital and experience design. A current model describing UX is the "umbrella" model by Dan Willis (Willis, 2016). This divided UX in Visual Design (choice of colors, shapes, etc.), information architecture (division of content, navigation paths, and search capabilities), interaction design (interaction between user and product), usability (effective, efficient and satisfactory achievement of goals) user insights and content strategy (user choice, intentions, affective and structured handling digital content)

Usually UX is used in metrics such as, success rate, error rate, abandonment rate, time to complete task and clicks to completion (success rate, error rate, dropout rate, execution time per task / activity, clicks to complete) are measured to assess the quality and performance of a product – but also, the image that forms in the user's head of the product as it uses or the proposed brand experience it becomes increasingly important: what associations and emotions are triggered during the use or user actions. UX thus refers to the experience of a digital product on a functional and emotional level (Scheier & Dirk, 2006).

Analyzing several research done by consulting companies like Watermark Consulting; Accenture and MCorp Consulting between 2016 and 2018 which compares the performance of the stocks of so-called "customer experience management leaders" with those of "CEM objectors". The CEM leaders and objectors are made up of the first and last ten listed companies from the "Customer Experience Index" of Forrester Research. The leaders include companies such as Amazon and AT&T and from the last ten listed United Airlines and Wal-Mart.

Five key criteria for a successful customer experience design have been extracted as follows:

Focus on more than customer satisfaction:

Fewer satisfied customers contribute to business success, neither through referrals nor through repeated purchases or lower price sensitivity. But even satisfied customers can switch to the competition at any time. To maximize the return on investment on CEM, companies need to create interactions that generate not only satisfaction but loyalty – for example weaving a narrative that place the user at the center of brand experience giving the impression of something larger than the user expects. As such the user will get a sense of purpose that should stem directly from the brand experience pushing to more immersive actions.

Ensure satisfaction and shine with small surprises:

To achieve excellence in customer experience it is important to master the multiplicity of customer satisfaction and experience design by minimizing customer frustration and annoyance. Based on this, it is wise to deliver "nice to have" elements and other positive surprises that lead to a special interaction experience between the brand and the customer.

Design special experiences specifically and emotionally:

Customer experience guides leave nothing to chance. It is mandatory to have a deep understanding of the brand and user touchpoints area and know how to play them. You have to specially choreograph interactions in such a way that they not only fulfill the rational expectations of the customers, but positively affect them in an interesting and impressive way.

Create user experiences using cognitive science:

Customer experience leaders often manage the reality and perception of their customer experience equally. They understand how user experiences brand interactions. In user experience design, properties which are self-visible for instance a triangle in picture, or the bold font of "their" in the above example, help to create focus which facilitates the cognitive activity of the brain and reduces the cognitive load as the user doesn't have to spend time searching for the relevant details. Users don't read the content they scan it – this is the reason, self-evident properties like different shapes, sizes, colors, fonts, orientations and so on are used to emphasize the main concepts – it is a commonly held belief that we can process 7 +/- 2 stimuli at once in our working memory, but there's plenty of competing research that suggest it is more about 4 +/- 1, or that we can group pieces of information together in a content set and thus, actually memorize better. So making targeted use of the findings of cognitive science it is therefore important in order to create positive and lasting loyalty-generating impressions.

Understand the relationship between User Experience and Brand Experience:

Happy and satisfied users become satisfied and loyal customers creating potential users (WoM). The value of this cycle cannot be overestimated - brand managers and UX managers frequently come into conflict mainly because nowadays following strict brand guidelines can lead to a poor user experience – the brand manager argues that content needs to be brand compliant in order to support the brand and the UX manager argues that a poor user experience harms the brand. Ultimately, this circular argument is the wrong conversation to be having. A brand's identity and a brand's user experience both

fall under the overarching umbrella of the brand promise. The brand promise includes the fundamental story, values, and positioning of the brand. With a well-defined brand promise, UX decisions can be driven by that promise and maintain a consistent brand even if brand identity elements aren't present.

User experience and user journey mapping

User experience map is not the same thing as a user journey map. They sound similar, but not exactly the same. A customer journey map outlines the touch points that consumers experience from first exposure to sale and even post-sale interactions with a brand. A user experience map takes it one step further, examining the complete picture of the customer experience with a brand, analyzing behavior and interactions across touchpoints and channels. Rather than a linear path from point A to point B, a customer experience map provides an understanding of the process that every type of target customer goes through when interacting with your brand, visually organizing every possible interaction a consumer could have with a brand throughout the entire buying journey (Hassenzahl & Tractinsky, 2006, p.91).

User Journey Mapping has its roots in Story Mapping (Battarbee, 2003, p.109), a well-known and proven method in Agile (Agile Software) development which gradually has been transformed into the User Journey Mapping method. In contrast to Story Mapping, which aims at collecting functions of the system under development, User Journey Mapping is focused on learning about relevant user processes and paths in order to identify areas with need for user research and development.

A user journey map is a research-based tool. It examines the story of how a customer relates to the business, brand or product over time. As you might expect – no two customer journeys are identical. However, they can be generalized to give an insight into the “typical journey” for a customer as well as providing insight into current interactions and the potential for future interactions with customers.

Customer journey maps can be useful beyond the UX design and marketing teams. They can help facilitate a common business understanding of how every customer should be treated across all touch points: communication channels, digital assets, sales, logistics, distribution, service, etc. This in turn can help break down “organizational silos” and start a process of wider customer-focused communication in a business (Chitturi et al., 2008, p.49).

They may also be employed to educate stakeholders as to what customers perceive when they interact with the business. They help them explore what customers think, feel, see, hear and do and also raise some interesting “what ifs” and the possible answers to them.

The aim of the method is to learn in a short time about relevant user processes and identify and plan necessary UX activities, even before entering the user research phase. Possibly all relevant stakeholders and knowledge carriers should participate in this workshop. This could be, for example, the product owner, the product manager, marketing manager, software architect, developer and a user representative.

A customer journey map is a very simple idea: a diagram that illustrates the steps your customer(s) go through in engaging with your brand, whether it is about a product, an online experience, retail experience, or a service, or any combination. The more touchpoints you have, the more complicated — but necessary — such a map becomes. Sometimes customer journey maps are “cradle to grave,” looking at the entire arc of engagement (Garrett, 2006, p.35).

Which are the important elements in creating a User Journey Map?

User-personas:

If you can't tell a typical user's story, how will you know if you've captured their journey? – Fictional characters reflecting the user types, pinpointing who they are and what they do with brand products in relevant contexts. Personas are distilled essences of real users. With personas, we build empathy with target users, focus on their world, share insights/knowledge with other stakeholders to gain consensus, make defensible decisions reflecting the persona's/user group's exact needs, and gauge our designs' effectiveness through their eyes.

A timescale:

Customer journeys can take place in a week, a year, a lifetime, etc., and knowing what length of journey you will measure before you begin is very useful indeed.

A clear understanding of customer touchpoint:

What are your customers doing and how are they doing it – customer touchpoints are places of interaction with your brand rather than “channels” which are planned points of interaction.

A clear understanding of the channels in which actions occur:

Channels are the points where an interaction takes place – from Facebook pages to retail stores. This helps you understand what your customers are actually doing.

An understanding of any other actors who might alter the customer experience:

For example, friends, family, colleagues, competing brands, etc. may influence the way a customer feels about any given interaction.

A plan for “moments of truth”:

These are the positive interactions that create good feelings in customers and which you can use at touchpoints where frustrations exist.

What Do Customers Expect from Touchpoints?

Appropriate (e.g. that both the context of the interaction and the cultural tone of the interaction meet the needs of the customer or user)

Relevant (e.g. that the function performed by the interaction meets the utility requirements of the customer or user)

Meaningful (e.g. that the interaction was perceived as important or purposeful by the customer or user)

Endearing (e.g. that the interaction created some form of bond with the user or customer for example through desirability, creating delight or a playful tone)

It's important to note that these are all things that can be designed – though it may take some user research to get to the bottom of how that design might take shape.

User experience mapping acknowledge the multitude of channels that customers interact with a brand throughout the buying journey in a more cohesive and comprehensive way. This is particularly important, as it's increasingly common for consumers to navigate across channels to make buying decisions and purchases. In response, brands must embrace omni-channel marketing – adopting a holistic view with the customer at the center, based on the understanding that today's consumers are navigating between a varieties of touchpoints to make purchases (Bevan, 2009).

Even multi-channel marketing falls short by treating individual marketing channels as stand-alone entities with their own strategies, which often results in a disjointed and distinctly different experience from channel to channel. The goal, and a goal that can be achieved with customer experience mapping, is to foster a consistent, positive experience across every channel and at every possible touchpoint throughout the buyer's journey.

Summary

User Journey Mapping is a creative method for a quick entry in complex UX projects. It allows us to learn in a short time about relevant user processes and identify and plan necessary UX activities, even before entering the user research phase. At a kickoff workshop with all stakeholders present, the User Journey Mapping takes about four hours of time and requires an experienced moderator to effectively lead the group in the process. In a slightly altered form User Journey Mapping can also be used in interviews. Either way, a successfully created user journey map serves to decide about user research activities and to prioritize the work on design concepts.

A major area of research is how a positive 'user experience' – or interaction experience – of the use of digital artefacts (e.g. web sites, applications, virtual experiences and digital assistants) can be promoted (Hassenzahl & Tractinsky, 2006, pp.91-97). This experience does not only include usability, but also other cognitive, socio-cognitive and affective aspects of users' experience in their interaction with artefacts, such as users' enjoyment, aesthetic experience, desire to repeat use, positive decision to use a digital artefact and enhanced mental models. Research in this area is timely because we are approaching the 'loyalty decade', where interaction experience will become the main success factor (Nielsen, 2008, p.79). Hence, the success of digital artefacts is to a large extent positively influenced by the extent to which they promote a high-quality experience in their users.

Furthermore, user experience (UX) manifests as quality in design, in interaction and in value, with diverse measures from many methods and instruments. One of the challenges related to UX is how to select appropriate measures to address the particularities of an evaluation context. The necessity and utility of UX measures is apparent, because such measures enable professionals to benchmark competitive design artefacts and to select appropriate design options. However, both the construct validity and predictive power of some UX measures are of particular concern. Consequently, modelling users' experience – as a basis for producing design guidance – is especially important. Generally speaking, two types of model are distinguished in the

behavioural sciences: whereas measurement models are used to measure the constructs in a particular domain, structural models are used to establish (causal) relations between constructs (Edwards & Bagozzi, 2000, p.309). These two types of model are indispensable to advance progress in a number of disciplines. First, sound measures need to be established with desirable properties (e.g. reliability, validity and sensitivity) to provide a sound basis for measuring UX. Second, explanatory or predictive structural models need to be developed – linking antecedents through behaviour to consequences – for the purpose of understanding, predicting and reasoning about processes of UX to inform system design.

Practical implications and conclusions

A series of research activities for understanding, scoping and defining UX have been undertaken in recent years, resulting in a broad but yet unconsolidated body of knowledge of UX. Apparently, the basic issue about the distinction between UX and usability requires a deeper and more systematic conceptual analysis. Identification of the uniqueness of UX does not imply abandoning the traditional usability approaches, which should actually serve as the base for incorporating some new requirements of UX.

In accord with the common understanding of UX as subjective, dynamic and context-dependent, UX measurement should essentially be self-reported, trajectory-based and adaptive. Traditional techniques such as questionnaire, interview, and think-aloud remain important for capturing self-reported data. With the advent of open-source, multimedia social software such as blogs and video-wiki (e.g. Law & Nguyen-Ngoc, 2008, pp.124-125), it has become increasingly practical to capture as well as share experience over a range of timeframes and contexts. However, what could be impractical are the resources required to analyse a huge body of rich experiential data that would result from such an approach. Further, a trajectory-based approach implies measuring various aspects of UX both in different contexts and at different points of time: user expectation (imaginary UX), user-affect (momentary UX) and user-emotion (long-term UX) (cf. Russell, 2009, p.215).

User experience is a multidimensional concept and a commonly accepted definition is still lacking. As (Hassenzahl & Tractinsky, 2006, pp.319, 689) argue, the concept of user experience attempts to go beyond the task oriented approach of traditional HCI by bringing out aspects such as beauty, fun, pleasure, and personal growth that satisfy general human needs but have little instrumental value. Therefore, when compared to basic usability, enjoyability plays an essential role in user experience. The extent to which an interactive product is enjoyable to use is referred to as the product's hedonic quality (Hassenzahl et al., 2000; Hassenzahl, 2001). The shift of emphasis from usability to experiential factors has forced researchers to consider what user experience actually is and how to evaluate it (Vermeeren et al., 2010, p.695).

It has been found that 'perceived usefulness' loses its dominant predictive power when applied to hedonic systems such as a movie website (Van der Heijden, 2004), and this is where perceived enjoyment becomes useful as a factor for explaining user acceptance. (Schrepp et al., 2006, p.1005) show that hedonic quality has also an important impact on the attractiveness of business management software that is used for work purposes. Companies see good user experience as being vital for continuous commercial success, especially since positive long-term user experience is believed to improve customer

loyalty. For example, (Garrett, 2006, p.37) and (Jordan, 2000, p.33) suggest that if people have delightful experiences with a product, they are more willing to buy the next product from the same company. Indeed, the results of (Chitturi et al., 2008, pp.48-63) show that delighting customers with hedonic quality improves customer loyalty in car owners, as measured by word of mouth and repurchase intentions, more than utilitarian quality does.

If enjoyment of hedonic quality plays an essential role not only in user experience but also in creating customer loyalty, the question then arises of what the appropriate timeframe for evaluating user experience is. Traditional usability evaluation methods focus on 'first-time' experiences with products and learnability (Courage et al., 2009; Mendosa & Novick, 2005).

Offline and online environments are increasingly converging and it will be of the utmost importance to look at these two worlds holistically, to merge them fundamentally. The focus is on the needs and experiences of the consumer that he has at any point of contact with a company or brand. The terms "customer experience" and "user experience" describe this point of view and are the focus of successful companies in their strategic orientation. They place the experience of a user with a company or its products at the center of consideration and, when used correctly, can make a significant contribution to added value. The holistic view of user experiences and marketing, the viewing of digital products like apps and websites not merely as information carriers, but as a concrete marketing tool, even as a brand ambassador, which deliberately trigger subconscious associations and emotions, is a fundamental prerequisite for fighting for the attention of the successfully succeeding consumers.

Abstract. *Positioning innovation in competitive markets is difficult. Finding the right balance of delivered value, development costs and market constraints is often a trial and error process. We propose a conceptual framework for framing innovation in a competitive landscape by addressing a key point that is crucial to coherent, effective and efficient innovation: the notion of Neglected Value. Neglected Value is the main driver of market adoption for segments that are currently not well-served by mainstream products. Identifying the Neglected Value for a given market segment, allows entrepreneurs to focus on the relevant value and thus minimize the waste (and cost) of irrelevant value. Delivering the neglected value must be done respecting the constraints, which if overlooked would jeopardize any possibility to penetrate the market. The Neglected Value is the essential component of the Innovation Canvas, a tool for designing innovation, which can be used both as an educational and a decision-making tool. This paper outlines the underlining of the Innovation Canvas and provides two business cases where the canvas can be applied. Moreover, the paper discusses a methodology for business development that is currently used in a university start-up pre-incubator.*

Keywords: *innovation; positioning; neglected value; value proposition; market gaps; business development.*

Introduction

In this paper, we introduce the new concept of Neglected Value, which represents the level of relevance of the value proposition for underserved customer segments. The creation of new value through innovation is often restricted to invention and creation of novel intellectual property. Unfortunately, frequent are the cases where intellectual property does not transfer to markets due to a missing relevant value proposition. We extend (and complement) the current approach of Osterwalder et al. (2010) for designing effective Business Models, especially in the Value Proposition Design approach (Osterwalder et al., 2014). For this purpose, we have introduced a new way of capturing customers' pains and gains by framing the market demand in relation with current offer and not as two separate things. Our approach integrates the elements of the Value Proposition Design approach with analysis of competitors that allows effective positioning of innovation in highly competitive markets (Ries & Trout, 1986).

We are considering the relationship between current (partially satisfied) demand and existing offer. We are thus focusing on problems rather than just on solutions. By framing value creation (hence innovation) through the Neglected Value concept, we can better articulate the architecture of complex business models (Teece, 2010) by combining multiple neglected values of multiple parties (customer segments and/or stakeholders). This provides the necessary first level of coherence of a business model, a foundation on which we can build the remaining parts of the model, such as Key Activities and Resources, Value Distribution, Customer Relationships, Cost structure and Revenue streams as defined by Osterwalder et al. (2010).

We present the Innovation Canvas tool for the identification of market gaps that can drive innovation towards real market needs (Mowery & Rosenberg, 1979), not necessarily manifested as an explicit demand for specific products. From our direct experience in the STarmac university incubator (Pallotta et al., 2017) and retrospectively in well-known business cases, we realized that market needs are rarely articulated directly by customers. In contrast, customers can easily express their current pains and expected gains with existing products. On one hand, at a certain point in a product's lifecycle, improving product performance is no longer sufficient to respond to new market demand. On the other hand, technology alone is insufficient for creating satisfactory products for a new market need.

We also believe that market-driven innovation (Hurley & Hult, 1998) usually spins off from existing market gaps where mainstream products fail to satisfy the specific demand of a customer segment. We do not want to call those segments "niches" because real niches tend to stay niches forever. A small underserved segment can grow bigger if the product performance grows beyond just satisfying the neglected value. For example, in the case of a digital camera, the technology evolved (thanks to its success in the initial segment: war reporters) to the point that low image quality was no longer an issue. At that point, the product could retain the best of the two worlds: the (initially) neglected value and mainstream products' performance. When this happens, the Tipping Point is reached (Gladwell, 2000), and the product/technology becomes itself mainstream.

We will discuss how identifying the Neglected Value is an effective way with the goal of creating a relevant new value proposition for underserved market segments, which would not benefit from products' performance improvement, but rather from radical or disruptive innovation (Christensen, 2015). We will provide some representative business cases where the concept of Neglected Value has naturally emerged and that was key to the success of bringing new products or services to the market (Rogers, 2003). The purpose is to illustrate how the framework works. In reality, the analyst will make assumptions that need to be validated with field research and market tests (Blank & Dorf, 2012).

Business model design and validation

Business Models are today key in modern innovation to leveraging enabling technologies for value creation and impact. Technological advances alone are not sufficient to trigger sustaining or disruptive innovation in industries and markets with multiple stakeholders such as those of Energy Management, Real Estate, Transportations, Banking, Insurance, just to cite a few. The reason lies in the complexity of the value chain, or even more precisely, value network (Biem and Casswel 2008).

Moreover, differentiation is very hard to achieve if only based on technology in highly competitive markets. With the advent of the Internet technologies, the usual dichotomy between producers and consumers no longer exists. As in Web 2.0, the profile of “Prosumers” emerged. Also, several ways of transferring assets over the Internet have emerged such as BlockChain and Smart Contracts (Christidis & Devetsikiotis 2016).

A Business Model (Trimi & Berbegal-Mirabent, 2012) can be defined as an architecture for creating new value for targeted customer segments in a viable and sustainable way. Business Model Design (Massa et al., 2017) is about linking together the components of the architecture in a coherent, effective and efficient way.

- Coherence is related to the interdependence of components, e.g. linked value streams, compliance with regulation and constraints, validated assumptions.
- Effectiveness has to do with impact and value creation. In other words, it's about pain relieving and gain creation for the targeted customers and/or stakeholders.
- Efficiency is about optimizing the resources needed for value/impact creation.

Although a logical structure exists, it is hard to reduce these three different views to discrete, independent components. Most of the time, in the case of multi-party business models (Evans, 2011), global optimality is hardly achievable. Rather, trade-offs are the norm. Moreover, as business models are designed before their deployment, their elements are mostly based on assumptions. Business models need to be validated first, before being implemented, so to reduce the risk of failure due to high uncertainty in assessing stakeholders' precise requirements. Markets are very volatile and framing conditions can be unstable and uncertain. Therefore, the design method must include ways to empirically validate the model in a reliable way, for instance simulating real conditions or with small-scale deployments. In the paper we propose a conceptual tool for positioning innovation in competitive markets and we also illustrate a validation methodology that has been adapted from the Steve Blank's Customer Development approach (Blank, 2006; Blank & Dorf, 2012) and from Eric Ries' Lean Startup method (Ries, 2011) to the validation of business models.

In order to better understand and avoid confusion on what we mean by effectiveness and efficiency, we outline three different situations where those concepts have a different understanding, namely Management, Manufacturing/Production, Innovation, and Business Development.

Management: effectiveness is about the quality of outcomes. In other words, maximizing KPIs. Efficiency is about minimizing costs or maximizing throughput. This can be done by optimizing processes through continuous improvement methodologies. Without entering in a long discussion, effective and efficient management deals with understanding the causal links between costs and revenues (also known as Returns on Investments), by optimizing the value chain and managing financial risk. This can be done either at the strategic or tactical level.

Manufacturing/Production: this is actually a special case of management where outcomes are products or artifacts. Here quality is very simple to grasp. Efficiency is achieved through the minimization of waste in the production lines. One can waste several types of resources at different levels. Time, for instance, is a valuable resource that can be wasted in case of re-work. Therefore, maximizing quality can be a way of both being effective and efficient. But time can be wasted because, in a production line, the capacity of the input in a step of the process does not match the output flow of the

previous step. Here is where the Theory of Constraints (Goldratt & Cox, 2004) applies: adapt the flow of production to the capacity of consumption.

Innovation and business development: in the case of business development, effectiveness is about achieving Product-Market Fit (Blank, 2006). Efficiency is about being able to achieve it with the available (limited) resources in a situation of extreme uncertainty, in another word, in a “lean” way (Ries, 2011). Here the key success factor is being able to de-risking through learning from (cheap and quick) validation experiments where relevant metrics are measured, which will allow the entrepreneur to take strategic decisions for rapidly converging to Product-Market Fit.

We noticed indeed that the effectiveness of the validation method depends on the type of risk, market or technological, and that we needed to find a trade-off between pure metric-based validation (Ries, 2011) and pure technology development (Dorf & Byers, 2008). The three fundamental perspectives in value creation, namely i) market desirability, ii) technical feasibility, and iii) economic viability cannot be tackled independently.

Figure 1. The sweet spot between different types of product's feasibility

More precisely, economic viability can only be assessed when the market demand (i.e. its size and intensity) has been fully identified as well as the costs of developing, deploying and marketing the product/service that would satisfy that demand (i.e. technical feasibility), as shown in Figure 1. This would allow two things:

1. understand that the perceived value of the new product in comparison of existing alternatives;
2. understand the business models that would provide sustainable, recurrent revenues ensuring a viable margin on sales.

Although we believe that desirability is the most fundamental one, we also believe that feasibility and viability must inform “how much” and “what kind of” desires we will provide to targeted customers. This is the reason why we had to come up with the

Neglected Value concept in order to grasp not only what should be done, but also what can be done and most importantly why.

For this purpose, an assessment of the type of risk is essential. We believe that for a product, risk ranges between two extremes: “pure technical” risk and “pure market” risk. We see very low chances of success to those products that feature both highly technical and market risk. In other words, if a solution to a problem is very hard to achieve, we expect that problem to be a compelling one (i.e. low market/adoption risk). This is almost always the case for drugs and health-related products (e.g. BioTech and MedTech). For the other extreme where market risk is very high (i.e. switching cost is very high), off-the-shelf technology should be more than enough to implement the solution as the main focus will be in understanding what exactly is the Neglected Value that would satisfy an unsatisfied need for an under-served targeted customer segment or stakeholder.

We have crafted a process that is depicted in Figure 1, which would eventually lead to the maturity level needed for scaling up the business. In (Pallotta et al., 2016) we have assessed the effectiveness of this approach by looking at relevant indicators related to entrepreneurs’ maturity. Also, the Innovation Canvas is currently in use by both students in our university who are involved in innovation projects and by our research laboratories’ spin-off.

Figure 2. The Business Model Validation process

Business model design should not end on paper. Building a business model architecture is only the first step of a, maybe long, series of iterations in adapting the made assumptions to the reality. Reality check is often a hurdle that engineers try to avoid, but which is extremely important for the creation of successful products.

The diagram is only an ideal path. It must be observed that when a pivot happens, depending on the seriousness of the issue, one would have to go back to the starting point and restart validating the new assumptions. We purposely put “feedback from experienced entrepreneurs” (also known as “coaches”) after the validations. We believe that coaches should provide feedback on real data not on subjective judgment based, as happens unfortunately too often, on just personal experience. Although this discussion

falls outside of the scope of the paper, we believe that in business what worked in the past might not (and usually does not) for the future, especially in innovation.

The innovation canvas

When innovating, most companies focus on features. This simply means that they maximize the number of features they can stick into a single product, often regardless of the value, they create. They assume that the more the features, the higher the number of customers will be attracted as more (and more diverse) value will be delivered. This might be a reasonable assumption because if one product is capable to satisfy more needs and desires, it will be purchased by more people.

Figure 3. The relationship between features and perceived value

For better illustrating the issues in efficiency and effectiveness of the feature-based approach in new value creation, we present a diagram Figure 3. This diagram represents the relationship between the perceived value and the number of features added to the product, which also correlates with development/production costs and time. There are essential features that are already present in existing products. These features create no “new” value and are expected by the customer¹. New value creation happens when added features differentiate the product from competitors’ products (i.e. through differentiating features). This will happen to a certain point and only for “relevant” features. After that point, added features will provide no added value to the customer. In other words, they will be perceived as “superfluous”. Unfortunately, adding more features increases development and maintenance costs (induced by accrued complexity) and does not guarantee by itself a return on investment. The resources needed to create/deploy those features are simply wasted.

The issue with the feature-based approach lies in the fact that not all features have the same impact on a customer’s adoption and therefore a prioritization is not only preferable but also needed for competitiveness. Only a few companies focus on overall delivered value from their products, regardless if they have all (or most) features implemented. They usually follow the ubiquitous Pareto 20-80 law where 20% of

¹ We will rename “essential features” as “hygiene factors” in the Innovation Canvas.

possible features will produce the 80% of satisfied customers. Moreover, it provides two additional advantages:

1. It leaves the product open for future improvements.
2. It reduces the product's complexity to its minimum.

Lean Startup (Ries 2011) advocates for value-based product development and it provides tools to measure (quantify) the value delivered to customers (and precisely to whom) with the product. However, it fails in providing a conceptual (and design) tool to prioritize value creation through the understanding of actual market needs by taking into due account the existing offer by competitors. The Innovation Canvas serves exactly this purpose. It helps in framing the value that is actually needed by the targeted market not only as an added value to existing products but also as a trade-off between necessary and unnecessary features.

The Innovation Canvas shown in Figure 4, has 8 components. The first three, are the obvious ones, namely the description of the Technology/Product, the targeted Customer Segment and the Existing Competition. It is important to notice that innovation takes place in a given context provided by the market in two fashions: customers and competitors. Without considering the existing (or even future) context, is hard to position innovation in an effective and efficient way.

Figure 4. The Innovation Canvas

In the remaining components, we consider 3 interlinked elements of the Value Proposition considering also the current competition, namely:

Neglected Value: the value that a customer segment or a stakeholder is currently missing from existing value propositions on the market. Usually, the neglected value represents "pains" for the customer segment or stakeholders, which prevent them to achieve their goals through existing "mainstream" value (i.e. products, services, technologies). In other words, the segment is *under-served*. We believe that effective innovation should primarily address unfulfilled compelling needs. This view does not necessarily limit to utilitarian (rational) needs, but it can be extended to more emotional and maybe

unconscious needs. Key is the way of how those needs are elicited, as they can be difficult to express when they are not yet manifested².

Tradeable Value: describes what type of value the customer segment or the stakeholder is ready to trade (or give up or sacrifice) in order to obtain the Neglected Value. We are convinced that it is extremely rare the case where customers can get better value at a substantially lower price of what already exists on the market. There is always a trade-off. Usually, for more value, the price is higher. For lower prices, the value is less. Our main point is understanding what can be conceded (or traded) for obtaining the relevant value, which can be missing today for the targeted customer segment or stakeholder.

Hygiene Factors: These are the constraints that need to be respected for enabling the adoption by the targeted customer segment. In other words, it is the existing value that cannot be traded for the Neglected Value. In some cases, hygiene factors do not represent themselves direct value for the customer or stakeholder, but their absence of them make acceptance of the overall value unacceptable. As a simple example, consider the value provided by Solar Panels. The Neglected Value is independence from the grid that for somebody is extremely relevant and necessary (e.g. houses and appliances in remote places). Traded Value is high-power and efficiency of panels. Hygiene Factors are power continuity (achieved through batteries) and reasonable operational cost.

These categories of values can be quantified and prioritized accordingly. For Neglected and Traded Value, we would suggest using metrics such as relevance, utility, etc. For Hygiene Factors, we can value the strength of those constraints. Of course, if a hygiene factor can be released (traded) it no longer belongs to that category and becomes traded value.

Depending on the type of Neglected Value, there are usually two possible cases of market penetration:

1. The creation of a New Market for that segment or stakeholder by providing them with relevant value.
2. When a too high price is expected, that prevents targeted customer segment to obtain the desired value. This situation can be described as “democratization” (or Low-End market).

The last components, Tipping Point reached, is simply an assessment of the status of innovation, or in other words, it provides an indication of its disruption power (and if the disruption has been achieved).

At this stage of analysis, we are considering the relationship between current (partially satisfied) demand and existing offer. We are thus focusing on problems rather than solutions. Methodologically, we recommend avoiding making assumptions on the solution’s technical feasibility and economic viability. These aspects are addressed in the remaining part of the Business Model (canvas). By framing value creation (hence innovation) this way, we can better articulate the architecture of complex business models by combining multiple neglected, tradeable values and hygiene factors of

² Relevant here is the quotation of John Ford’s « if I asked customers what they wanted, they had told me: faster horses ». If re-framed as Neglected Value, certain users of horses were in strong need to travel faster. Not every horse owner switched to cars. Only those who were compelled to do that because they were underserved by horses.

multiple parties (customer segments and/or stakeholders). This provides the necessary first level of coherence of a business model, a foundation on which we can build the remaining part of the model, such as Key Activities and Resources, Value Distribution, Customer Relationships, Cost Structure, and Revenue Streams.

Case studies

We present two examples of retrospective analysis with the Innovation Canvas. We fully understand the limitation of retrospective analysis, but the purpose is only to illustrate how the framework works. In reality, the analyst will make assumptions that need to be validated with field research and market tests.

Digital photography

The first example is a case of New Market creation induced by the introduction of Digital Camera technology. We all know the story that Digital Cameras were invented in Kodak labs. In Figure 5, the first ever digital photo taken was made by a prototype developed at Kodak. Although they invented it, they failed in understanding the value of digital photography just because it could threaten their core business model based on the sale of films and supply for chemical processing of them and for printing. Digital photography did not take off overnight and did not replace immediately chemical photography. This disruption took more than 10 years to occur.

Figure 5. First picture was taken with Kodak digital camera prototype
(Source: https://en.wikipedia.org/wiki/Digital_camera)

Today, digital cameras are the standard technology for photography, but back in the '80, the situation was completely different. Early manufacturers of digital cameras had to figure out which segment of the market to target in order to make this invention valuable, thus turning it into a real innovation. The segment is chosen (or more probably that had early adopted this technology) turned out to be that of "War Photo-Reporters". At that time, their requirements were not fully met by ordinary photography technology. What we now call the Neglected Value for them was the need of getting rid of the time spent in developing films and printing pictures taken on the war field and have them ready to be sent as fast as possible to the journal through faxes. Removing this pain was essential to them. The digital camera offered this value to the expenses of reduced image quality. The question was then: were they ready to "sacrifice or trade" image quality for more convenient use of the camera? Today we know that the answer was Yes, but at that time we guess that it was not so clear to determine what the Tradeable Value exactly was. For sure, it was not framed that way.

In retrospective, we can easily understand that key factors for adoption were how fast picture could be sent to the journal headquarter. The faster the image was available for printing, higher were the chances to get copies of newspaper sold. Image quality was not actually a key factor because pictures' quality was eventually degraded during the transfer through the fax machine, and besides, the image quality of printed on the newspaper was not in general very high.

Concerning the constraints that need to be met for war photo-reporters, we imagined that some sort of reliability of the memory and long-enough battery life need to be guaranteed. In Figure 6, we filled the Innovation Canvas with the above-discussed elements. Since the innovation was based on differentiation from the existing products, we frame it as New-Market. Of course, we can observe that the Tipping Point for this product has been reached.

Figure 6. Innovation Canvas for the Digital Camera technology

Low-cost airlines

The second example is a case of the Low-End market. Low-cost airlines (https://en.wikipedia.org/wiki/Low-cost_carrier) are a typical example of Business Model Innovation where the value for customers is created through an innovative way of cutting or mutualizing costs. This case is less technology-driven than the Digital Camera one, but nevertheless equally disruptive. After the introduction of low-cost airlines, the aviation business has completely changed. Today, the only existing model for airlines companies is low-cost. All airlines have switched to this business model. However, casualties derived by this new disruptive business model are rather traveled agencies. Traditional airlines were able to easily imitate this model and get through the disruption. It was not the case for the process of disintermediation that killed travel agencies. Therefore, the Tipping Point is reached. The Innovation Canvas for Low-Cost airlines is shown in Figure 7.

Figure 7. Innovation Canvas example for Low-Cost Airlines

For Low-End markets, the only relevant Neglected Value is (affordable) Price. Everything else is accessory. Customers simply could not afford the existing product or the service because of its price. To get an affordable price, are they ready to “trade” some value? Which one? The answer was (and still is): yes. There are several features that can be excluded from the ticket without dramatically affecting the flying experience, namely: luggage allowance, meals, and snacks, Business Class, booking through a travel agency, paying only by credit card, flying to peripheral airports, etc. What is interesting are the constraints that need to be guaranteed: The Hygiene Factors. We assume that nobody would fly with an airline which would not guarantee flight safety, for instance lowering aircraft maintenance costs or using old airplanes. We also suspect that punctuality has to be guaranteed, although is a less stringent constraint than the previous one.

Conclusions

In this paper, we have discussed a key element of the Innovation Canvas is the notion of Neglected Value, namely value delivered to market segments that are currently underserved by existing products or services. The Innovation Canvas is a conceptual tool for position innovation in competitive markets. We have also outlined a methodology for validating business models which integrates the Innovation Canvas tool as a scoreboard for tracking value creation and achieving product-market fit.

We think that a new product or service cannot be both better and cheaper than existing competitors’ products or services. We rather believe that market-driven innovation usually spins off from existing market gaps where mainstream products fail to satisfy the specific demand of a customer segment. It is not unusual that an initially small underserved segment can grow bigger if the Tradeable Value for obtaining the Neglected Value can be reduced and eventually eliminated to serve the mainstream market. This is exactly when the Tipping Point is reached. For example, in the case of a digital camera, the technology evolved (thanks to its success in the initial segment) to the point that low image quality was no longer an issue. At that point, the product could retain the best of

the two worlds: the (initially) neglected value and the tradeable value. When this happens, the product/technology becomes itself mainstream.

In the context of the STarmac pre-incubator, we noticed that the Innovation Canvas tool is a good companion for the Value Proposition and Business Model canvases because it helps the innovators and entrepreneurs in positioning their value proposition with respect to existing competitors' products or services. Moreover, it helps them in formulating hypotheses on value relevance for targeted customer segments. We observed that a quick reality check is done by linking pains and gains to existing market offer, which leads to the precise identification of market gaps and underserved market sub-segments. For the moment, the appreciation of the effectiveness of Innovation Canvas in detecting and framing market gaps comes only from qualitative observations. Users of the Innovation Canvas have mostly provided a positive feedback on its use, especially on the fact that the tool forces them to search for real issues of existing products for targeted customer segments by focusing more on the "why" aspects rather than on the "what" and "how" aspects in product and/or business development.

As next steps, we envisage providing a better-outlined validation process with a set of pre-defined experiments that can be executed to validate the Innovation Canvas hypotheses. Quantitative experiments to prove the effectiveness of the Innovation Canvas results will be conducted and data collected in the framework of the STarmac acceleration program Business Validation.

GAME THEORY IN STRATEGIC MANAGEMENT. THEORETICAL AND PRACTICAL EXAMPLES

Mihail BUȘU

National University of Political Studies and Public Administration
30A Expozitiei Blvd., Sector 1, 012104 Bucharest, Romania
mihail.busu@facultateademanagement.ro

Abstract. *Game Theory provides an analysis tool for describing the decision-making process of one or more players, their behavior when there are plenty of possible outcomes. Strategic behavior is a generic term that designates all concerted and consistent actions promoted by an enterprise in order to influence the competitive environment or at least to adapt to its evolution. This paper aims at exploring the real potential of strategic management based on game theory decisions and illustrates that the usefulness and power of game theory applied in strategic management lie in its ability to provide insights on competitive climate and strategies. In this paper, we will investigate some potential contributions of game theory to strategic management, especially with regard to applications in individual industries. The examples presented in the second part of the paper are based on strategic management decisions that involve dominant strategies.*

Keywords: *strategic management; game theory; dominant strategies; Nash Equilibrium; consumer behavior; oligopoly.*

Introduction

Strategy is known as a valid or applicable pattern of behavior in a given competitive context. It is a way of positioning the company, as a result of strategic thinking, at the intersection of the best solutions "matching" key competence of the company with a situation predictable competitive environment.

Over the years, there were many definitions of strategy. Chandler (1962) defined strategy as "the determination of the basic long-term goals and objectives of an enterprise, and the adoption of courses of action and the allocation of resources necessary for carrying out the goals". Ansoff (1965) comprised strategy in four components: growth vector, product market scope, synergy, and competitive advantage. Leonard et. al. (1969) defined strategy as a pattern of purposes, objectives, goals and major policies, as well as the plans for achieving the goals, determined in such a way the enterprise is or is going to be.

The strategy was also defined as the examination of the sources of efficiency which make enterprises successful, like innovation, diversification, new product development, acquisitions, corporate governance etc. (Camerer, 1991). In addition, Porter (1996) mentioned that strategy is realized fit between enterprises activities.

Organizational values are the preferences and beliefs of the leaders, while corporate social responsibility is about the ethics of the community in which the enterprise is embodied (Mitzburg, 1990). Strategy is further elaborated through generic strategy typologies of Miles and Snow (1978) and Porter (1980, 1985).

Game theory is a branch of applied mathematics that addresses the problem of optimal behavior in games with 2 or n people. Game theory is an abstract model of decision making; should not be confused with an explanation of decision making in the social reality. The common point of all the imagined games within the theories is the idea of strategy. Game theory is an interdisciplinary approach to studying human behavior. The most involved disciplines in game theory are mathematics and economics, but also other social and behavioral sciences. Game theory was created by mathematician John von Neumann.

Shubik (1972) argues that the solution concepts resulted from game theory could be thought to us as descriptive view or normative of multi-person decision making. Game theory could also describe the analysis of rational behavior in situations where interdependence of outcomes is involved (Martin, 1991).

Game theory studies how decision-makers are making their decisions (Camerer, 2011). Game theory can be used to show how decisions are made in various areas, such as politics, economics or sports. In the last two decades, game theory has been used by economists to analyze a wide variety of interactions and economics (Myerson, 2013). The organization industry main interest is to analyze the competitive interactions between oligopolies and game theory helps us understand these interactions (McCain, 2014).

A game includes players, strategies, profits, result, and equilibrium. All these elements define the rules of the game. The following definitions help us to better understand the theories of games:

- Players are the decision makers. In our examples, players will be two or more oligopolies or a monopolist and a possible new entrant who is already on the market or about to enter.
- The actions include all the possible decisions of a player.
- Strategies are rules that tell every player what action to choose in each stage of the game.
- Profits are expected profits for each player to get at the end of the game.
- Equilibrium is the result of choosing the best strategy, a combination of strategy and that each player could choose.

Using game theory, the economists are seeing a picture with participants in the game, certain rules that define certain decisions (Colman, 2013). The results of the game - what each participant receives - refers to his earnings and depends on what each player does. Each participant in the game has a strategy and he decides what strategy to apply. In games where each participant has the chance to take more than one decision (where there is more than one round), decisions may depend on what happens in the previous round. The game theory begins with the hypothesis that every participant in the game is rational and knows that his rival is also rational (Aumann, 2017). Each competitor is trying to maximize his own gains. Theory tries, thus, to predict what each player will do. The answer depends on the rules of the game and its earnings.

Strategic thinking does not only help to "frame the way" like a television show. We all face situations that require strategic thinking. Economists are trying to understand the

choices that people and businesses make. The range of economists has spread to other areas (i.e. politics, sports) by studying strategic behavior (Jeung et. al., 2016).

Economists study the choices made by rational individuals and profit-maximizing enterprises. In the basic competition model (perfect competition), individuals and businesses do not need to act strategically. Consumers and businesses can buy and sell at the price of the market. An enterprise should not take into account the reaction of its competitors if it decides to produce more. The same situation could be true in a monopoly market, but for another reason: the monopolist has no competition. In the basic monopoly competitive model, the strategic behavior - decisions that take into account the possible reactions of others - does not play any role.

Things are different in the situation of an oligopoly. With only a few companies in the industry, each business must take into account the reaction of the competitors, whenever they think to expand the production or lower the price.

In game theory, to study the cooperation of the companies into an oligopoly market, the aim it is to understand strategic decisions and understand how the organizations would behave when they know that their actions are influencing the behavior of others. For example, when the managers of a major airline decide to modify the price of travel tickets on a particular route, they should consider how their competitors could react to this price change.

Similarly, the competitors should react when deciding how they will react, given that the company who was the first to change the price of the market, will react in some way to the decisions of the other company. These are strategic decisions, just like players' decisions in various game categories like chess, football or poker.

Dominant strategies

By strategic behavior, it means that each player needs to know what the other player is going to do. Will you or your accomplice confess? If you cut prices, will your competitor react the same way? The decision a player takes depends on how he thinks the other player will react.

In the prisoner's dilemma game, we assume that players are guided by the following reason: "For every decision I make, what is the best choice the other player can make?". In analyzing the prisoner's dilemma, we ask:

- If Prisoner A does not confess, what is the best strategy for Prisoner B?
- If Prisoner A confesses, what is the best strategy for player B?

In both cases, we can conclude that confession is the best solution for Prisoner B. If B's best solution is to confess, no matter what prisoner A will do, then A will assume that B will confess, so A has to decide which is the best solution he can have if B confesses. So, the best solution for Prisoner A is also to confess.

Confession is the best strategy that both prisoners can follow, no matter what the other will do. This strategy - which works best no matter what the other player will do - is called dominant strategy. As we recall, the goal of game theory is to predict which strategy each player will choose. When a player has a dominant strategy, this is the strategy that a rational person should follow.

Nash equilibrium

It is easy to guess the end of the game - its equilibrium - whether the player has a strategy to do. Everyone will play his dominant strategy. Therefore, in the game of the prisoner's dilemma, equilibrium is achieved when recognition of their deed is made by the two players. The situation is not at all easy when only one of them has a dominant strategy or when none has such a strategy. To predict the final results in these complex games, we need to reconsider the reason why confession is a balance situation in the prisoner's dilemma.

In the prisoner's dilemma, each of the two prisoners confesses, because it is to his advantage to reach the optimal result - the lowest period spent in prison - taking into account the testimony of the other. The result is balanced, meaning that no one will change its strategy if he would get the chance. By confessing, both chose the best solution. Such a balance is called Nash equilibrium and is one of the basic tasks in studying game theory.

Prisoner's dilemma occurs in many situations, both in economy and social sciences. The following examples will demonstrate this.

Negative advertising campaigns

Why do companies engage in negative advertisement campaigns against each other, although they promise not to do so? Let's look at the case of two companies A and B which are selling a similar product on the same market. If none of them will run an advertisement campaign, the customers will have a good opinion of both, but none will gain an advantage over the other. If both are making negative advertising campaigns, the customers would percept both companies in a negative way and none will gain an advantage. Both are affected by each other's campaign. If the company A does a fair campaign, company B can gain an advantage carrying a negative campaign that affects A. Conversely, A wins conducting a negative advertising campaign if company B is running a fair campaign.

In Figure 1 we could see the payoff matrix for the advertising campaign.

		Company B	
		Positive campaign	Negative campaign
Company A	Positive campaign	X X	+ -
	Negative campaign	- +	X X

Figure 1. Advertising campaign

Every company would motivate its decision: *"If my opponent carries a negative campaign, I will gain a better image if I'll take a negative campaign. And if my opponent does not carry a negative advertisement campaign, then I can gain an advantage if I run a negative advertising campaign. In any case, I will be better off if I have a negative electoral campaign"*. Each politician has a dominant strategy and there is only one Nash equilibrium in which both companies carry out a negative electoral campaign, despite promises not to do so.

Sports club managers and players employed

Sports teams compete for the best players. Suppose there are only two important teams in a national championship: A and B. If both teams make an agreement to keep small wages for their players, the owners will make big profits. If the owner of Team A, instead, provides high salaries, while owners of Team B does not, then Team A will attract all good players and generate large profits for their employer. Meanwhile, Team B will eliminate all the expensive players and will have a weak season. Low concern makes the sports club owner lose money. If Team B will offer high salaries and Team A not, then Team B will take all the good players and win big profits, while Team A will lose money. If both clubs offer high salaries, no team will have all good players, and employers will have lower profits due to wage growth.

In the Nash equilibrium, both team owners offer players high salary and get lower profits than they would be able to understand to keep wages low.

Zero-sum games

We consider a simple game played by two ice-cream managers: Dan and Paul. They both sell ice cream in a kilometer-long park. Everybody wants to park his truck at a point where he would have the best view. There are three possibilities for each truck parking: entry, mid and out of the park. Where will like each truck?

We consider the three possible locations. Table 1 shows the possible sales percentages for the two vendors, depending on the location chosen.

Table no.2. The profit matrix of the two sellers

		Truck Location 2		
		entry	middle	exit
Truck 1 location	entry	50, 50	25, 75	50, 50
	middle	75, 25	50, 50	75, 25
	output	50, 50	25, 75	50, 50

If both locate the same point, the vendor's sales fall 50-50. But if one sits in the middle and the other on one of the two ends, then the first one will get 75% of the sales, while the other will get the remaining 25%. Both vendors have the same possible options and think as follows: *"If the other ice cream truck sits in one of the two ends of the park, then for me the best thing would be to get positioned in the center and get 75% of sales. However, if another truck will sit in the center, then for me the best thing would be to get all position the center to split sales 50-50, otherwise, I only gain 25% of sales while my*

competitor would take the remaining 75%. So, no matter where you park the other truck, it's best for me to sit in the center".

Thus, the Nash balance is reached at the point where both sellers park their trucks in the center of the park.

The above game has an important feature: in each situation, the sum of the sales of the two ice cream trucks is 100%. For each 1 percentage point increase in sales of the first truck will be a 1 percentage point reduction in sales of the second truck. Such a game, in which the accumulation of a player is reflected in the loss of another, is called zero amount game.

A suitable solution for all zero amount of games is achieved using the so-called minimax strategy. If the first seller chooses a strategy that minimizes the winnings of the second one, then he will have a dominant strategy. Thus, the first vendor finds out if he is parking in one of the two ends of the park, then the other seller will park in the middle and collect 75% of the sales. Therefore, the first seller's minimax strategy is to locate in the middle, which minimizes sales of the second seller to a maximum of 50%. The same strategy, seen from the perspective of the second seller is to maximize the minimum achievements of every game possible. As low as 25% when located either at the beginning or at the end and 50% when it is located in the middle, means that the second seller will also be located in the middle.

Applications of Game Theory in strategic management

In the prisoner's dilemma, players have a dominant strategy. This is not the case in most games. What each player considers to be best for him, depends on what the other player does. This makes it even harder to predict the end of the game. But often, we can anticipate the end of the game thinking of the consequences for each player, as we did for prisoner's dilemma.

Games with one dominant strategy

To illustrate how we could foresee the end of a game, even when one player has a dominant strategy, we consider the case of two companies who decide on reducing or increasing prices. The two companies, Discounter Deluxe, and Quality Brands are rival and compete with each other. Deluxe promises to their customers the lowest prices and therefore will lose many customers if they fail to offer them. Brands have higher costs and would prefer not to reduce prices. However, if Brands does not align with Deluxe's price reduction, it risks losing a big share of its turnover.

The results each one expects to have is shown in Figure 3. The annual turnover for Deluxe are shown below the diagonal line, and Brands are shown above the diagonal.

Figure 3. The game of price reduction

		Quality Brands	
		Reduces prices	Does not reduce prices
Discounter Deluxe	Reduces prices	\$2.5 mil \$5 mil	\$1 mil \$6 mil
	Does not reduce prices	\$3 mil \$1 mil	\$3.5 mil \$2 mil

Deluxe has a dominant strategy – to reduce prices. It has more to gain with this strategy than Quality Brands does. The latter, on the contrary, does not have a dominant strategy. If Deluxe reduces prices, it's better for Quality Brands to reduce prices as well, given that otherwise it would lose too much in sales. Also, if Discounter Deluxe does not reduce prices, then for Quality Brands it would be much better not to reduce prices.

Even though Quality Brands does not have a dominant strategy, we could see the end of the game if we argue as follows. Quality Brands knows that Discounter Deluxe will reduce prices since this is Deluxe's dominant strategy. Therefore, the fact that Quality Brands would think it would be best to keep the prices high if Deluxe does the same thing, is irrelevant. Quality Brands knows that Deluxe will reduce prices. The best strategy of Quality Brands is to reduce prices as well. The outcome or the equilibrium in this game will have both companies if they will reduce their prices.

In this price reduction game, each company is following its best strategy, given that the other company follows its best strategy to reduce prices. Reducing prices is the only and only Nash equilibrium. Because of the strategy of the other player, none of them wants to change its strategy.

Games without dominant strategies

Both the game of the prisoner dilemma and the game of price reduction have a single Nash equilibrium. However, often a game will have more than one Nash equilibrium, as shown by the following example.

We will study the case where two friends decide to study together. Both are enrolled in the same physical and economics courses, and both believe that performance on future tests will improve if they study together. Still, John would prefer to use his time concentrating on physics, while Todd would prefer to devote his time to the economy. The game board for this case is shown in figure no. 4, where the notes express the environments obtained by the two students in the two subjects (the note written underneath each diagonal of each box is the reward for John).

		Todd	
		Studying physics	Studying economics
John	Studying physics	X X	+ -
	Studying economics	- +	X X

Figure 4. The game of the study

Has any of them a dominant strategy? Not. If John insists on studying physics, Todd would benefit if he would join John in studying physics books unless he continued to study the economy alone. On the other hand, if John consents to study economics, then Todd's best answer is to study economics. Similarly, the best strategy of John is to study economics if Todd does the same. No player has a dominant strategy, best for each being the same thing the other one does.

Even if there are no two dominant strategies in this game, there are two balances Nash - either physics learners or both studying economics. Although the concept of Nash equilibrium may not lead to a unique equilibrium in the game, it can help remove effects.

Neither the upper-right and bottom-left boxes on the chart do not represent a Nash equilibrium. If Todd is studying physics, John's best answer would not be to study economics.

Conclusions

In the markets with perfect competition, businesses and consumers can decide how much to produce and how much to consume, without taking into account how they can react the others. In markets with imperfect competition, firms need to keep in mind the way they react competitors in the company's production or price decisions. Companies have to behave strategically in such conditions. People also face many situations where they need to act strategically. Economists use game theory to predict how businesses and individuals act. In fact, the perfect competition model works only in theory.

The prisoner's dilemma shows that our own interest can prevent people from maintaining cooperation, even if it is in the common interest. The logic resulting from the prisoner's dilemma applies to many situations, including the arms race, advertisements, common resource issues, and oligopolies. A Nash equilibrium exists if all players do their best to know the choices their opponents have.

In the case of Nash equilibrium, each participant in a game follows the best strategy, taking into account the strategies followed by the other players. A game can have a unique equilibrium point or more equilibrium points.

A dominant strategy is the best strategy a player could follow, taking into account what the other players might choose. In a zero-sum game, the minimax strategy is the dominant strategy of the game. Oligopolies maximize their total profits by forming a cartel, behaving like a monopoly. Therefore, if oligopolies' individual decisions about production levels, the result is a lower price than that resulting from a cartel.

Abstract. *The article investigates the Zara clothing brand of the Spanish Inditex company known for the clothes that always enjoy high demand. The article aims to study the competitive strategy of Zara, its ability to adapt to the changing business environment, as well as to define the major competitive advantages in comparison with the direct competitors. Inditex has a number of brands in the low-price, middle-price, and the high-price segments of the clothing market. The authors analyze the competitive positions of Inditex in the middle-price segment of the Russian clothing market, with the Zara brand as the most popular one among the customers. The market is selected for the case study, because being one of the most promising regional markets, it is at the same time challenging for a European producer due to differences in consumer preferences and purchasing patterns. The authors' approach of the analysis is based on Porter's five forces of competition. Numerical score is used to evaluate the threats of intra-industry competition. It is concluded that the Russian women's clothing market is characterized by a high level of saturation, tough competition, and slowing pace of growth. The authors identify the main competitive advantages of Inditex in comparison to the direct competitors: Benetton, Marks & Spencer, H&M and GAP. Inditex is the market leader, with Zara securing half of the company's market share, thus being the most recognizable clothing brand in many countries of the company's presence. The success of Zara proves that the company's strategy is adaptive and competitive. At the same time, the analysis reveals changes in the business environment. The buyers are currently focused mainly on offline shopping. However, Zara's main competitors develop online stores and delivery services. As estimated by the authors, the threat of intra-industry competition is high; competition with online stores will be increasing. The threat of new players entering the clothing market is estimated as high. The threat of losing consumers of the Zara brand is estimated to have an average degree. The threat of loss of suppliers is low. The authors propose managerial tactics and formulate development strategy basics. The paper presents the following opportunities for Zara promotion: increasing online sales, expanding sales through large outlets and closing small stores, preserving the existing solutions and searching for new ways of differentiating the brand, reducing costs by developing clusters of suppliers.*

Keywords: *Porter's five forces of competitive position; clothing market; Zara brand; competitive advantages of Inditex; intra-industry competition level.*

Introduction

The Russian market of women's clothing retail accounts for 5% of global sales, making it a large and attractive market. Thus, it is not by coincidence that Russia has become a field of competition for clothing suppliers from many countries from all over the world. Expansion of international clothing retailers in Russia contributed to the fact that 85% of Russian consumers prefer foreign brands of clothing. International retail chains prevail in the Russian clothing market. On the other hand, national brands are strengthening their positions. It should be noted that 71% of the buyers usually buy clothes in the shopping malls (Alto Consulting Group, 2013). Alto Consulting Group (2013) found out that twenty-one percent of consumers in the Russian women's clothing market preferred to buy clothes online in 2013. This share is increasing every year. The trends prove that the market is developing providing new opportunities and challenges for the producers and retailers.

The competition is increasing primarily in the middle-price segment of clothing retail. It has shown a significant drop in demand during the decline in sales in 2014-2016 due to a decrease of the income level. The share of the middle-price segment of the Russian clothing market has declined from 40% in 2011-2013 to 30% in 2015-2016. (Gafarova, 2017, p.12). Consumers of the middle class have partially switched to relatively cheap brands.

With the market downturn, the positions of major suppliers have changed; the intensity of competition has increased. Some luxury brands were forced to leave the Russian market. Gafarova (2017) lists the clothing retail chains with the largest number of outlets in Russia in 2016: O'STIN, Gloria Jeans, Tvoyo, INCITY, Sela, Inditex, and OGGI. Inditex (Industries in Design in Textiles) of Spain is the only foreign company among the brands listed. Inditex managed to maintain its share in the Russian clothing market, primarily due to the popularity of the Zara brand, which belongs to the middle-price segment, as well as due to the availability of brands sold at reasonable prices.

Inditex has a number of brands: the low-price segment includes Bershka, Stradivarius, Pull & Bear trademarks, the middle-price segment includes Zara and Oysho, and finally Zara Home, Massimo Dutti and Uterque belong to the high-price segment. Zara has been the most popular brand in Russia compared to the other brands of Inditex. According to InfoLine Analytics (2012), the Zara brand accounts for 49.5% of sales of Inditex in Russia. The success of the company is attributed to the ability to capture fashion trends, borrow them and turn them into reality at attractive prices (O'Shea, 2017, p.19). Not only does the company carefully study consumer preferences and the latest trends in the fashion industry, it adapts the production process to customer requests. This approach allows the company to reduce the costs and the value creation chain, and keep the prices low. Inditex designs clothes and offers them at a reasonable price by constantly updating the design. The company itself is engaged in the design, storage, distribution and logistics (Guan & Zhang, 2011).

Most of the European clothing retailers have seen decreasing financial indicators at the beginning of the 21st century. In particular, Marks & Spencer has reduced the number of its own stores in the UK and abroad. Operating profit of Marks & Spencer in foreign markets fell by 39.6% in 2016 (Zykova, 2017). GAP originating from the US is reducing the number of outlets in Europe. Zara seemingly has not been affected by the industry recession. On the contrary, the revenues of Inditex have been increasing by 20% annually. The popularity of Zara stores allowed Inditex to avoid excessive advertising (Gamboa & Goncalves, 2014). Advertising costs of the Spanish company make up only 0.3% of the revenue. For comparison, competitors spend 3-4% (Ferdows, Lewis & Machuca, 2010).

Methodology

The objectives of the study include analyzing the main competitive advantages of the company, identifying the threats and proposing short and middle-term managerial solutions.

The model of the five competitive forces by Porter can be used to analyze the competitive strategy. The five forces include rivalry between existing firms, the threat of new competitors, the market power of the buyer, the threat of substitutes, the market power of suppliers. The forces together determine the intensity of competition and profitability (Porter, 2015). As Porter points out, any company seeks a position in the industry, which will allow it to protect itself from these competitive forces or influence them with profit for themselves (Porter, 2015, p.38).

The authors implement a system of numerical scores to evaluate the most important indicators of the five competitive forces of competition based on the approach proposed by Motorina (2013).

The threat from substitute goods is evaluated using a 3-point scale where 3 points mean that the market is characterized by a high threat from substitutes:

- 3 points if the market has substitute products and they secure a large market share;
- 2 points if the substitutes have just entered the market and the market share is small;
- 1 point if the presence of substitutes can be neglected.

The threat of intra-industry competition is also evaluated on a 3-point scale for four indicators:

- number of companies in the market: 1 point if there are not more than 3 companies, 2 points for an average level of concentration (4-10 competitors), and 3 points if competition is more intense;
- market growth rate: 1 point if the growth rate is high, 2 if the growth rate is low, and 3 points if the sales volume is decreasing;
- product differentiation: 1 point if the market has standard products, 2 points if competing goods have only main consumer properties standardized, and 3 points if the clothes are highly differentiated;
- the possibility of price increase in the market: 1 point is assigned if the market allows setting higher prices and increasing profits, 2 points if the price increase can only cover the increase in costs, and 3 points if there is no possibility of increasing prices.

The scores on the four indicators mentioned above are summed up. Thus, the maximum is 12. If the score is not more than 4, then the threat from competitors is estimated as low. If the score is more or equal to 9 points, then it is considered that the market is characterized by a high threat from current competitors.

The threat of losing consumers is evaluated with the use of four indicators:

- the share of large buyers: 1 point is assigned if the sales volume is evenly distributed among all customers, 3 points if more than 80% of sales are attributed to only several customers;
- buyers' willingness to switch to substitutes: 1 point if the product is unique, 2 points if the product has distinctive features, and 3 points if the company's goods have full analogs;
- buyers' price sensitivity: 1 point in case of absolute insensitivity to the price, and 3 points if buyers always switch to a product at a lower price;
- customer satisfaction with product quality: 1 point for full satisfaction, 2 points if there is dissatisfaction with secondary features of the product, and 3 points if there is major dissatisfaction.

The company has an average threat of losing current consumers if the sum of scores above falls in the range of 5 to 8 points. The score of 9 to 12 points signifies a low probability of losing consumers.

The threat of new rivals entering the clothing market is evaluated with 8 indicators:

- economies of scale: 3 points are assigned if the clothes production doesn't enjoy economies of scale, 2 points if only a few companies can achieve it, and 1 point for a large-scale effect in the industry;
- the share of brands on the market: 3 points are assigned if there are no large players in the market, 2 points in case of 2-3 large players occupying half of the market, and 1 point if the biggest companies secure 80% of the market;
- differentiation of brands and consumer segments: 3 points are assigned if the diversity of goods is low, 2 points if there are micro-niches, and 1 point if all the most important segments of the market are occupied;
- level of investments and entry costs: 3 points if the investment pays back in 1-3 months, 2 points if the payback period is 6-12 months, 1 point when the payback period exceeds 1 year;
- access to distribution channels: 3 points if full access is available, 2 points if it's partially limited, and 1 point if there is no access;
- government policy: 3 points if there are no acts and regulations limiting activities, 2 points for a low level of state intervention, and 1 point for a high level of state involvement;
- companies' willingness to reduce prices: 3 points if they do not tend to reduce prices, 2 points when only large companies are ready to cut prices down, and 1 point the trend of price reduction affects all the major companies;
- clothing market growth rate: 3 points if the growth rate is high, 2 points if the market is slowing down, and 1 point in case of a downturn.

The market is characterized by a high threat from the new entries if the sum of the 8 indicators ranges from 17 to 24 points. If the total score is not more than 8 points, then the degree of threat is considered low.

The threat of losing suppliers is evaluated with four indicators against 2-point scales:

- number of suppliers: 2 points are assigned there is a monopoly or a small number of suppliers, 1 point if there are many suppliers;
- suppliers' limited resources: 2 points if resources are limited, 1 point if there are no definite limits;
- costs of switching to other suppliers: 2 points if costs are high, 1 point for low costs;
- priority of the industry for suppliers: 2 points in the case of low priority, 1 point if the industry enjoys high priority.

If the company has long-term relations with suppliers and the sum of scores for all the four indicators is less than or equal to 4 points, then the threat of instability of supply is low. The total score of 7-8 points signifies a high threat of suppliers switching to other companies.

A combination of analytical and expert methods is used to assign scores. Indicators are evaluated on the basis of analysis of the industry statistics, analytical reviews published by consulting companies, information available online from the major clothing manufacturers and other sources of secondary data. The group of experts included 5 sales managers at the Zara store in Yekaterinburg, Russia.

Evaluation of the level of intra-industry competition in the Russian clothing market for Inditex (the Zara brand)

The secondary data analysis suggests that the direct competitors of the Zara clothing brand are large international companies focused on the middle-price segment: Benetton, Marks & Spencer, H&M and GAP (Table 1).

Table 1. Comparative parameters of the main competitors of Zara in the Russian clothing market (middle-price segment) (Source: authors' elaboration [1])

Parameter	Zara	H&M	Marks & Spencer	Benetton	GAP
Country of Origin	Spain	Sweden	The United Kingdom	Italy	The USA
Foundation year	1985	1947	1884	1965	1969
Number of outlets	2000	2800	885	6200	3500
Number of countries of presence	50	49	40	120	90
Production	Predominant own production, 6500 factories	No own production	Own production and outsourcing	Own production and outsourcing	No own production
Retail chain	Own	Franchising	Own and franchising	Franchising	Own and franchising

Parameter	Zara	H&M	Marks & Spencer	Benetton	GAP
Brand value	Produce what customers want to buy	Fashionable clothes at a reasonable price for those who like to change clothes often	Great variety for all customers	Bright and cheerful colors	Quality every day, natural materials
Differentiation	Constant updates of collections and high speed of delivery, adherence to the newest trends in the fashion industry. High level of vertical integration	Fashion, economy, sociality. Preservation of natural raw materials by recycling old clothes, inviting famous models to take part in advertising campaigns	Development of innovative fabrics and clothes for all preferences, large advertising costs, attracting famous designers, stars and fashion models to advertising	The first self-service shops, innovations, special style of models. Provocative and bright advertising	Omni-channel sales, leadership in sales through the Internet, investments in the development of consumer personalization tools in customer databases

According to the experts' estimations, H&M lost the lead as the largest seller of clothing in the world in 2016 [2]. Inditex has become the leader, and its share in the global clothing market is increasing. Net profit for the fiscal year of Inditex grew by 10% at the beginning of 2017. The company's active growth in emerging markets and the development of online sales offset the negative effects of currency fluctuations (Dahan & Peltekoglu, 2011). Figure 1 presents a comparison of the net profits of the main competitors.

Figure 1. Net profit of companies in the world clothing market for 2016, million dollars [3]

The analysis shows that the Russian clothing market is highly saturated and has an oligopolistic structure. Inditex still manages to retain its leadership in Russia. At the same time, it is likely that in the long term the share of Russian clothing manufacturers will increase. Consumers tend to switch to the domestic product due to the weakening ruble and decrease in the effective demand. According to Euromonitor, Inditex is the largest player in the Russian apparel market with a share of 2.7% for 2016 [4]. The figure seems promising especially if compared to the shares of domestic competitors: Sportmaster – 1.7% and Gloria Jeans – 1.5%.

In addition to the fastest update of the collections, the important differentiating feature of the Zara brand is the location of the stores. Outlets are located both in the shopping malls and as mono-brand stores in the central streets of major Russian cities near-luxury brand boutiques. In an attractive environment, consumers of Zara can try clothes on, getting help from young, fashionably dressed consultants. The situation is different from traditional retail chains. Zara can deliver new products to its stores around the world in 2-3 days, using only air and road transport. Much attention is paid to the definition of consumer preferences. Designers of Inditex visit the major cities of the fashion industry and carefully monitor the latest trends. The product range of Zara often offers analogs of Prada, Dior, Alexander Wang, Marc Jacobs, etc., which have just appeared on the catwalks (Willems et al., 2012). The company's multi-brand system is another differentiating advantage. The idea of making copies of the fashion models of famous couturiers and selling them several times cheaper turned out to be successful and attracted buyers with different incomes and different social status.

Competitive advantages of Inditex

The vertical integration of all divisions and efficient distribution can be considered among the main factors of the company's success. It is also one of the main reasons for the company's stability during the market downturn and the growing popularity of online shopping. The following competitive advantages of the company can be identified.

1. Effective implementation of a client-centered approach, based on the studies of the needs of the buyers. All employees of the company are involved in the research process from the seller in the store to the designer and top management. The company has identified the trend: a modern consumer is keen to follow the fashion of each new season updating the clothes frequently and at a reasonable price. Six hundred designers travel around the world in the search of the latest trends. After the introduction of a new collection of clothes, Zara monitors the wishes and the choice of consumers and continues to produce the lines that enjoy the demand (O'Shea, 2017, p.100). Advertising slogans support the client-centered approach e.g. by the telling customers that there is no need to worry if they make a mistake when choosing clothes, as the company will refund the money (O'Shea, 2017, p.90).

2. The "fast fashion" concept (Martínez, Errasti & Rudberg, 2015). All business processes of the company pursue the main goal – to meet the demand of the buyers in the shortest possible time. Zara has revolutionized the fashion world and the textile industry; the cycle of marketing clothes is only 2 weeks in the company with the industry average being 8 months. Inditex creates redundant production capacities that remain unloaded for most of the time, but allow the production of products that are in high demand to be set up very quickly. As noted by Ferdows, Lewis & Machuca (2010), Zara makes major

investments, ensuring that the network of factories and distributors provide the fastest response to changes in demand. The company often changes collections, ensuring fast delivery of products, promptly increases the production of clothing, which consumers show interest in. For the same reason, half of the fabric produced by the company is not painted, color decisions are taken during the season, considering the reaction of consumers to the proposed colors of a particular new collection. Goods are supplied by distributors with price tags, go to stores, and are immediately made available for purchase. The company has proven that efficiency in all parts of the supply chain allows for less inventory: for Zara, the stocks are equal to 10% of sales, while for Benetton, H&M and Gap – 14-15% (Porter, 2015). Compared to GAP and H&M, the Inditex business model has a higher degree of vertical integration.

3. Attracting talented designers to the company's staff. The company spends a lot of money to pay creative employees. It has a relatively large staff of designers who often monitor the solutions of the world's leading fashion houses. Clothing retailers accuse Zara of copying, plagiarizing the most outstanding seasonal trends, but this does not prevent the company from gaining momentum and leaving its competitors behind (O'Shea, 2017, p.18).

4. Efficient information support for a vertically integrated business model. Zara pays special attention to the introduction of the latest information technologies that simplify information exchange. It helps to enhance the quality of modeling, production, and distribution of clothing. Specially designed pocket computers are used to transmit both objective data (new orders, changes in sales dynamics, etc.) and subjective information: descriptions of the reaction of buyers to certain products, their feedback on novelties (Ferdows, Lewis & Machuca, 2010). Regardless of the sales region, the information system allows retailers to transfer systematic data and individual examples of customer preferences and wishes to designers and manufacturers.

5. Leadership, ideas and managerial talent of the company's founder Amancio Ortega. He has brought to life the simple philosophy: everyone can dress well. Ortega came up with an innovative business system of fast fashion, based on his own design studio and the desire to produce what customers want. He proposed a vertically integrated system of production, distribution and retail sales. Ortega's personal qualities contributed to the phenomenal success of Zara. He has the mentality of a consultant in a store, having started his career with the lowest position in sales (O'Shea, 2017).

Determining the competitive strategy of Zara in Russia

The Russian clothing market has a tough competition of brands. A study conducted by the Department of Psychology of the Higher School of Economics identified the respondents' commitment to foreign and Russian brands in the middle-price and low-price segments (Antonova, Kumar & Soloreva, 2016). The ranking is based on the frequency of references to the brands preferred by consumers. Zara has the highest recognition level (63 points). The main competitor of Zara is H&M (38 points), but due to the fact that Inditex has a large portfolio of brands, the number of loyal customers is increasing faster (Royo-Vela & Casamassima, 2011). There are several large players holding about 50% of the Russian clothing market. The loyalty of consumers to these brands is much higher than for other ones in this price segment.

Considering the way retail sales are organized, substitutes can include second-hand shops, discount-markets, and online stores. A significant proportion of consumers are increasingly interested in purchasing clothes online. Nevertheless, consumers do not tend to switch to online shopping completely. Online shopping is fast; however, it often does not provide an opportunity to try the good on when buying. Thus, consumers risk spending more time to replace the good or get a refund if they do not like the product.

Consumers of the middle-price segment remain loyal to the preferred brands of clothing and do not seek to save some money by switching to other brands. However, with a decrease in the level of impulsive consumption, the frequency of purchase is also decreasing. In a highly saturated market, consumers mostly remain satisfied with the product range. At the same time, there is dissatisfaction with the quality of the goods. Ten percent of the respondents note that the quality of the clothes they purchase is not always satisfactory. The reasons may include unstable color or discrepancy in size (Krug, 2016).

Inditex feels confident in its supply chains. According to the official website of Zara, the company with its 6500 factories cooperated with more than 1800 suppliers in 2016. Inditex has a significant advantage – ability to negotiate with suppliers and maintain strict requirements for price, quality, and speed. The company cooperates with internal and external auditors, who evaluate all the suppliers for compliance with the company's requirements. Inditex is engaged in the creation of clusters, which integrate all the suppliers to improve overall performance (Zhang, 2008a; Zhang, 2008b).

Table 2 presents scores of the five forces of competition in the clothing market and the direction of increasing the competitiveness of Inditex (the Zara brand) in the Russian market.

Table 2. Score of the five competitive forces in the Russian clothing market for Zara
(Source: authors' elaboration)

Competitive force	External factors	Competitive strategy
The threat from substitute goods is high (3 points) The main threat is associated with online stores operating in the same consumer segment.	There is an increase in online purchases: 21% of consumers buy clothing online. In addition, the share of discount stores, second-hand stores, and clothing markets are relatively large – about 50% of the market.	The company aims at the development of online sales. Online sales account for 6% of Inditex profit. Consumers can reduce the intensity of purchases, but it is unlikely that they will switch to the low-price segment.
The threat of intra-industry competition is high (5 points) There is an increase in the market share of domestic companies (Sportmaster, Gloria Jeans) and competitive pressure from foreign competitors.	The market share of Zara is estimated at 2.7% as of 2016. The Russian market has large clothing retailers, which are direct competitors of Zara (Benetton, H&M, etc.).	Inditex needs to find unique ways of differentiating the brand. The perception maps of all Inditex brands, obtained through customer survey, allow us to identify the main instruments of differentiation for the Russian market.
The threat of losing the company's consumers is average (7 points):	Despite the tough competition, the company holds its market share, mostly because of the	The main strategic directions: to preserve the differentiation of Zara brands and keep prices at the current

Competitive force	External factors	Competitive strategy
- the sales volume is evenly distributed among all customers (1 point) - the company's products are partially unique, there are distinctive characteristics important for customers (2 points) - buyers will switch to other brands only if there is a significant difference in price (2 points) - dissatisfaction with the secondary characteristics of the goods (2 points)	popularity of the Zara brand. Inditex has also brands aimed at both the lower (Zara TRF) and the upper (Zara Woman) parts of the middle-price segment, which helps in keeping a large number of loyal consumers.	level (mainly for the lower part of the middle-price segment).
The threat of new rivals entering the clothing market is high (17 points): - Economies of scale are significant (1 point) - strong brands with a high level of awareness and loyalty occupy more than 50% of the market (2 points) - there are micro-niches (2 points) - the average level of initial investments and entry costs for the industry, payback period of under 1 year (2 points) - access to the distribution channels is open (3 points) - large players will not reduce prices (2 points) - the growth rate of the Russian clothing market is slowing down (2 points) - there are no restrictive acts from the state authorities (3 points)	Barriers to market entry can be considered relatively low; the level of investment and entry costs are moderate, there are ways to differentiate the product, access to distribution channels is open, antitrust policy is effective.	Constant monitoring of the new rivals, not only in the international market but also in the Russian market, targeting the same market segment.
The threat of losing suppliers is low (4 points): - wide selection of suppliers (1 point) - no distinctive limitations on the resources of suppliers (1 point) - low switching costs (1 point) - a high priority of the industry for suppliers (1 point)	About 40% of Zara's materials are purchased from Comditel, a member of Inditex. Zara accounts for 90% of Comditel sales. Zara dictates the terms of cooperation to suppliers.	Improving the cluster organization of the company's suppliers' business.

The company's website presents a strategic plan of the marketing strategy. There is no need to have many clothing stores with the growth in the number of Internet sites, providing the means for online shopping. Like other international clothing retailers, Inditex is focused on reducing the number of small stores, expanding larger outlets with the favorable location, as well as developing online sales (Mahonin, 2017). According to Societe Generale, Internet commerce is becoming the company's main strategic guideline. The expansion of traditional Zara stores slowed down in 2016-2017, which proves the conclusions of the analysis.

Conclusions

The study shows that the phenomenon of the Zara brand is attributed to its value: to produce the clothes that consumers want to buy. Amancio Ortega has built a unique business model, integrating the processes of design, production, distribution and retail sales based on the concept of fast fashion, which allowed the company to reduce the time from designing to selling clothes and to change collections often. By following the latest trends in the fashion industry, including copying famous fashion designers, the company meets the needs of buyers with different levels of income, but firstly, the middle-price segment.

Zara is the most recognizable brand in Russia. The company is ahead of the competing international clothing retailers. The scoring of competitive forces allowed the authors to conclude that the threat of intra-industry competition in the Russian clothing market is high, demand is slowing down, and suppliers are forced to reduce prices. Consumers of the middle-price segment mostly remain loyal to brands, but reduce the number of purchases.

The threat from the substitute goods is high, firstly, from the Internet shops. Twenty-one percent of Russian consumers already buy clothes online.

The threat of losing consumers is estimated as average for Inditex. The Zara brand has differentiated value, unique characteristics in the perception of consumers. The buyer will switch to other brands only with a significant difference in price and/or quality of clothing.

Strong brands with high loyalty level account for more than 50% sales in the Russian market. At the same time, the threat of new rivals entering the market is high as the payback period of investments is under one year, and there are micro-niches still open for newcomers.

The threat of losing suppliers is estimated as low. Inditex forces the terms of cooperation to suppliers, many of them being a part of the Spanish company.

The analysis of intra-industry competition shows that the Russian clothing market is highly saturated. Increase in price is possible only in the context of cost recovery. Competing clothing brands seek to differentiate themselves through additional advantages and constant updates of collections, as well as with the development of omnichannel sales. The threat from the main competitors inside the industry (Benetton, Marks & Spencer, H&M, and GAP) is high. Apart from that, the market share of Russian brands is growing in the context of the ruble devaluation.

Inditex takes actions to retain its market share. Competitive strategy in the Russian market provides for increasing online sales, closing small stores and expanding sales through large outlets, preserving and searching for new ways to differentiate the Zara brand from competitors, keeping prices at the current level mainly at the lower end of the middle-price segment.

FACTORS INFLUENCING CUSTOMER'S CHOICE OF INTERNET SERVICE PROVIDERS IN ALBANIA

Ana BUHALJOTI

University of Tirana

Arben Broci St., 1000 Tirana, Albania

ana.buhaljoti@gmail.com

Abstract. *The internet service in Albania has been growing steadily over the past decade. The internet availability is key to enhancing competitiveness and sustaining economic growth. Internet service providers (ISPs) have grown significantly and the internet market in Albania is expanding. While the speed of technology acquisition is increasing, the power of service differentiation is gradually decreasing. ISPs do not differ much on the service provided. The first step in increasing competitiveness is to understand why customers choose a particular service provider. Thus, this study aims to identify the factors that affect consumers purchasing behavior. It aims to investigate and understand how a range of factors impact the customers' perceptions to choose their current service providers. The research paper explores the factors that influence customer choice towards Internet Service Providers in Albania by using a quantitative method via a questionnaire survey. The findings of the research present the factors affecting the consumer's choice of an Internet Service Provider in Albania. It is showed that brand image is the most influential factor in the selection of ISPs. In order to gain new customers, internet providers have to take into consideration the company's image as a critical factor to the consumer decision-making, followed by the information disposed to customers and the risk associated to the service provider. The research provides high-speed internet providers in Albania insights on how to acquire new customers.*

Keywords: *customer choice; decision making; Internet Service Providers (ISP); perceived risk; information; brand image; Albania.*

Introduction

All people on earth are consumers, and are considered the most powerful people in the business world, as they possess the power of choosing to buy a product (Blythe, 2013). Thus, it is important for companies to understand the factors that affect the decisions of the consumer. Internet service providers are trying to acquire new customers and also keeping existing ones. The more users a provider has, the lower its average unit cost will be, and the higher its operating performance (Hu & Hwang, 2006). Due to the Internet market liberalization, internet providers have rapidly increased in Albania. The internet expansion and high-content consumption are important factors for the rising demand towards high-speed internet offered by ISPs. Albania appears to have an internet penetration level higher than the world average, which is 46.5%, but lower than the European Union where online penetration has exceeded 79%. The country with the highest percentage of internet usage is the US with 88% (World Insta, 2016).

The reason for the growth of internet consumers is related to the global trend of rapid growth of internet usage, market liberalization and a positive pressure exerted by government instances, especially for business. Electronic procurement, tax payments

and other fiscal facilities through the Internet have positively pressured the rise in demand for Internet service in Albania.

Currently, about 25 ISPs operate in Albania. The largest are Albtelecom, ABCom, Tring, and Abissnet. ISPs are part of a competitive market but do not differ much in the services offered. According to the Electronic and Postal Communications Authority, the number of subscribers to fixed broadband networks amounted to 143 thousand. The major provider is Albtelecom who owns 40% of the retail fixed broadband market while among the alternative fixed operators, ABCom has the largest number of broadband connections with a 21% market share (AKEP, 2016). Although the number of Internet access service providers is large (25 active local operators), the four largest operators own 84% of this market.

Thus, understanding of customer decision-making or customers' choosing behavior is very important for the service providers in order to find out how to acquire customers and make them repurchase. Other studies show that customers tend to compare the elements of different providers and search for several sources of information to help reduce the perceived risks in their choice (Parasuraman, Zeithaml & Berry, 1984). Also, a good brand image turns out to be a competitive advantage. Customer choice is influenced by the reliability of the brand (Wang, Lo & Yang 2004).

This paper aims to find out what variables influence consumers to purchase their ISP by reviewing key factors in the sector. It illustrates consumer patterns in purchasing Internet Service Provider (ISPs).

Literature review

Consumer behavior is described as the processes involved when an individual or a group is buying or choosing a product or a service to satisfy needs and desires (Solomon et al., 2013). The processes are five: problem recognition, information search, evaluation of alternatives, purchase and post-purchase.

The problem recognition is likely to occur when consumers realize there is a gap between their desire situation and the actual one and consumers desire to fix this gap. Once the needs are recognized, consumers enter the second stage to search for information about products or services. A consumer can use either internal or external search (Schiffman & Kanuk, 2007). External source arises from the outside environments, such as marketing, commercials, and friend's suggestions. Internal source refers to information stored in consumers' memory such as past experience and relevant knowledge about the brand (Senecal, Kalczynski & Nantel, 2005). The collected information allows consumers to do a comparison among different alternatives. The evaluation of alternatives assesses purchase alternatives which are in relation to important attributes of products or services. The consumer is valuing different alternatives and uses an evaluating criterion to compare brands, products, and services. A consumer sees a product or a service as a combination of different attributes. Attitudes, beliefs, and intentions are also often mentioned as factors that can influence the alternative evaluation (Darley et al., 2010; Solomon et al., 2013). This is particularly relevant in today's developed economies where consumption is almost like an ideology and there is a substantial increase in the supply.

After evaluating all alternatives, consumers choose which product or service is the most suitable and appropriate for their needs. The last stage of the decision-making process is post-purchase which regards the post-evaluation of the purchase, where the consumer is evaluating how satisfied the purchase and the use of the product is. In this stage, the consumer forms an intention to buy the most preferable alternative.

Depending on the model of Blackwell, Miniard and Engel (2001 – see Figure 1), the decision of the consumer is influenced by two variables: (1) Environmental influences: culture (the knowledge, skills, traditions and customs which define a set of individuals), social class (group of individuals who share the same social position by having the same income or the same job), personal influences (attitudes, beliefs, behavior, and opinions from references groups with an individual serves as an example), family (2) Individual differences: consumer resources (time, money and information), motivation and involvement (the need to fill and the satisfaction), knowledge (the information known by the individual), attitudes (elements that an individual holds to assess a brand like feelings, knowledge, and intentions to purchase) and the personality, values and lifestyle (Blackwell, Miniard & Engel, 2001).

Figure 1. The decision-making process (Source: Blackwell, Miniard & Engel, 2001)

The last stage in the traditional decision-making process is post-purchase behavior, which regards the post-evaluation of the purchase, where the consumer is evaluating how satisfied he is with the purchase and the use of the product (Solomon et al., 2013). Customer satisfaction with the purchase is determined by how tightly consumers' expectation is linked with the perceived performance of the product. A satisfied consumer is more likely to spread positive word-of-mouth and information received through word-of-mouth are more credible than a commercial advertisement (Darley, Blankson & Luethge, 2010). As previously underlined this paper aims to investigate what factors affect purchase intentions for Internet Service Providers and specifically what influences the selection of ISPs in Albania.

Consumer choice theories

Consumer choice can be described as "selection, consumption, and use of products and services". Before making a choice, the customer chooses to combine information with previous experiences, information available at the time of purchase, and trusts that he has created over the brands (Solomon et al., 2013).

Based on the rational choice theory the consumer has sufficient ability to calculate which option will maximize its value. He collects information on the attributes of the alternatives and chooses the best option according to his criteria. Current studies show that consumers do not engage in a rigorous rational choice. The researchers noted three types of consumer choice patterns: a) emotional choice, b) choice based on attitude and c) attribute-based choice (Hawkins & Mothersbaugh, 2010).

a) The emotional choice is based on the reliability of the service brand. Studies show that credibility is more important than expertise in making the choice (Schiffman & Kanuk, 2007). Brand choice is not only influenced by the personal perception of the consumer over the brand, but by some other marketing factors, the situation, or past consumer experience.

b) Attitudinal choice includes the general use of attitudes, impressions, intuition, consumer use in the selection without examining attributes. An attitude is accepted as a judgment. Studies show that attitudes are easier to keep in mind than the particular attributes of brands (Kardes, Cronley & Cline, 2011). Time pressure is the key determinant as the consumer make decisions based on its attitude.

Most individuals collect very little information from outside sources before a purchase. In a stand-alone choice, consumers make brand ratings based on everything they know about brands and then choose a brand for which they have the highest rating. According to Kardes, Cronley and Cline (2011), consumers make their choices based, generally on impressions of a brand and sometimes on the particular brand attributes.

c) Attribution-based selection requires customer recognition of the attributes of all brands. This choice is based on the comparison of each specific attribute of all brands taken into consideration. The easier it is to gather information on brand attributes, the more difficult it is to use attribute-based choice. (Kardes, Cronley & Cline 2011)

When consumers make attribute-based choices, they compare the specific features of each brand and choose the brand that best performs the key attributes required. In cases of almost similar brands, it is easier to distinguish if specific attributes are compared.

Factors of customers' choice of internet service providers

Customers' choice is the process of customers' choosing among alternatives that lead to buying the service. There are many factors that contribute to the customer's choice. Based on previous studies, information search is considered central to decision-making theory. Information search represents the second stage of the decision-making process and it influences a customer's product choice. Customer choice is influenced by product information availability and prior experience with the products. It is shown that the greater the degree of perceived risk, the more effort consumers expend to seek

information. The degree of uncertainty associated with services can be reduced by using several sources of information. McColl-Kennedy and Fetter (1999) grouped information search into two broad activities, the sources of external information and the degree of effort involved. Sources of external information are categorized according to whether they are dominated by marketing or whether they are dominated by personal and impersonal communication. They can be controlled by the (1) market (2) reseller (3) third-party independent; (4) interpersonal sources; and (5) by the consumer. Consumers' external search effort is measured by the number of stores visited, the number of brands examined, and the time spent in the overall shopping experience. Mitra, Reiss and Capella (1999) confirm that consumers prefer personal information sources than impersonal information sources.

The level of information collected by the customer is interrelated to the factor of perceived risk. Perceived risk refers to the nature and amount of risk perceived by consumers regarding a particular purchasing situation. Srinivasan and Ratchford (1991) define perceived risk as the probability of any loss (financial, performance, physical) that can occur due to the absence of external search, multiplied by the importance of that loss. Forsythe and Shi (2006) studied and investigated the types of risk perceived by internet buyers when they intend to purchase. They suggest that there are three types of risks: performance risk, financial risk, and time/convenience risk. Product performance risk refers to any loss which occurs when a service does not perform as expected. Financial risk is defined as the potential net loss of money involved. Time/convenience risk refers to the inconvenience or difficulty which occurs during the process of purchase transactions (Forsythe et al., 2006).

A distinguishing factor that reduces perceived risk and facilitates customer selection is a corporate image. Corporate image can be viewed as the outsider's perception of a particular organization (Chun, 2005). Customers' perceptions of the corporate image depend on overall past experiences and interactions with the brand. Chun (2005) suggests that corporate image is the outsider's perception whereas corporate reputation derives from both internal and external stakeholders' perceptions. The distinction between image and reputation is useful because one can form an image of a corporation without any real experience of it. Compared to reputation, corporate image is quicker to change under the influence of advertisements. Some researchers suggest that companies with a good reputation and image have a competitive advantage and are likely to acquire more customers (Gotsi & Wilson 2001; Grardberg & Fombrun, 2002). Corporate image is established and developed in the customers' mind based on communication and experience and has an impact on customers' judgments. Building a corporate image is a lengthy process that can be improved by the successes and achievements of the company.

In the telecommunication market, the extrinsic characteristics such as personal contact, the physical environment, technical support, and the responsiveness of the staff of service providers can have significant influences on customers' intentions to select a service provider (Nguyen & Leblanc, 2001). The interaction between service provider and customer, along with the encounter processes can also have a strong effect on customers' behavior (Athanasopoulos & Iliakopoulos, 2003). Customers consider corporate image prior to service choice as it can help them to evaluate the ability of the service company to fulfil their needs.

Based on the literature review, the customer choice result from a combination of information disposed of, previous experiences, perceived risk, and brand image. This paper aims to understand and evaluate whether these factors influence a customer's choice of internet service providers in Albania.

Methodology

This research aims to explore the factors influencing customer choice of Internet Service Providers in Albania. Based on the literature review a theoretical frame was developed with the main factors identified in order to test whether they are relevant to the Albanian market. Specifically, to understand whether the customer choice of internet providers in Albania is influenced by information disposed of, previous experiences, perceived risk, and brand image. The primary data collected on consumer behavior tend to evaluate consumers as rational. For identifying behavioral factors, researchers rely mainly on the survey method (Sekaran, 2003). The survey questionnaire consisted of questions on a Likert scale of 1 to 7 (where 1 is 'Strongly disagree' and 7 is 'Strongly agree') and determined approaches to choosing a high-speed internet service provider, experience with the high-speed internet, future intention towards service providers; and demographic questions. The survey was conducted face to face and increased the level of trust and cooperation between interviewer and respondent (Sekaran, 2003). The face-to-face survey is considered more appropriate for Albanian culture because respondents can better respond if direct instructions are given and assisted through the survey.

The target population of the study is internet users aged 16-55 who have home-based Internet connections. According to Electronic and Postal Communications Authority, the number of subscribers to fixed broadband networks at the end of 2016 was 242,870 inhabitants. Taking as 95% confidence level and 5% margin of error, the population sample is calculated to 400 individuals. The sampling method is a probability in proportion to size. The probability of an individual to be selected is proportional to the size of the cluster to which he belongs, giving greater clusters greater probability of selection and small groupings the lower probability.

According to AKEP, the number of subscribers with broadband access from the fixed network has an inappropriate distribution by regions Tirana 49%, Durrës 10.2%, Shkodra 6.85%, Vlora 6.6%, Korca 6.2%, Fier 6.1%, Elbasan 4.1% as shown in Table 1.

Table 1 *The national distribution of the sample*

Region	Number of subscribers with Broadband access	Index by region size	Sample
Vlorë	16,149	0.07	27
Tiranë	118,954	0.49	196
Shkodër	16,647	0.07	27
Lezhë	8,253	0.03	14
Kukës	2,454	0.01	4
Korçë	15,134	0.06	25
Fier	15,047	0.06	25
Gjirokastër	5,252	0.02	9
Elbasan	10,590	0.04	17
Durrës	24,803	0.10	41

Region	Number of subscribers with Broadband access	Index by region size	Sample
Dibër	3,236	0.01	5
Berat	6,309	0.03	10
Total	242,828	1.00	400

Respondents are selected randomly. Every third person in the main city centers is selected for an interview. This allows all members of the targeted population to have an equal chance of being included in the sample. The randomly selected respondents had to meet the criteria of using the internet service at home and fall in the users age group 16-55 years old. The questionnaire was distributed to the public areas of the counties where a large number of Internet users could be found.

The sample at the end resulted in 430 individuals who answered the questions on a seven-point Likert-type scale from 1 to 7 (where 1 means "Strongly Disagree" and 7 "Strongly Agree").

The data collected through the questionnaire includes internet user profile, choosing an internet service provider, experience with the internet service provider and perceptions of the service. The collected data was analyzed via Statistical Package for the Social Sciences SPSS.21 and the main data analysis includes descriptive analysis, factor analysis, correlation analysis with a correlation coefficient (Pearson), and multiple regression analysis.

Analysis

The findings of this study derived from a well-structured questionnaire consisted of questions on a Likert scale of 1 to 7 (where 1 is 'Strongly disagree' and 7 is 'Strongly agree'). The analysis includes customer attitudes for choosing a high-speed internet service provider and experience of the respondents with the ISP.

The distribution and profile of the 430 respondents who participated in this research are presented in table 2.

Table 2. Number of respondents by regions

	Frequency	Percent	Valid Percent	Cumulative Percent

Total	430	100.0	100.0	

Figure 2. Age

The group of 430 respondents includes internet users from the age of 16 to 55. Most of the respondents (62.6%) belong to the age group of 16-25 years, while 22.3% are 26-35 years old. Other age groups (36-45 years) and (46-55 years) account for 15.1% of respondents. Studies show that the age group 16-25 is the broadest segment with access on the internet.

Figure 3. Education

Respondents were asked about the highest level of education they have completed. It is shown that 51.6% of respondents have completed university and 17.4% have a master / doctoral degree, while 29.1% have completed high school. International statistics show that university-educated users represent the largest number of Internet users. Thus, the education of respondents reflects the education of internet users. The employment profile matches the age profile of the internet users. The level of employment is an indicator and social status of internet users.

Table 4. Experience of respondents with Internet companies

		Frequency	Percent	Valid Percent	Cumulative Percent
1. Who is your current service provider?	Do not know	26	6.0	6.0	6.0
	Abissnet	29	6.7	6.7	12.8

Figure 4. Internet Service Provider of connected households

Albtelecom brand as the market leader has the advantage of national coverage and infrastructure ownership, while other operators have coverage in the main regions of the country.

Respondents use internet access at home for more than 3 reasons. Based on their answers the first reason is communication (to communicate, for e-mail), the second reason for education (to read/inform) and the third entertainment (for video/music, to download movies/books, to play). Work accounts for a small percentage.

Respondents were asked about the frequency of using internet (every day, 2-3 times a day, once a week, once every two weeks and once a month) at each access point and the average hours they spend every time they hook to the internet (less than one hours, 1 hour, 1-2 hours, 2-3 hours, 3-4 hours and more than 4 hours). Monthly hours spend on the internet were calculated per user by multiplying the frequency of usage for each access point with the average hours spend when accessing the internet in the specific access point. Most of the respondents (63%) have high usage rates, spending over 4 hours a day on the Internet.

Figure 5. Internet usage rate

Factors affecting customer choice of ISPs

Table 5 shows the values of the matrix of the coefficients for the complex variable "Consumer Choice". Its determination is made with the help of the PCA method and the Promax rotation method with Kaiser Normalization and serves to predict consumer behavior. There are 3 Eigen values greater than 1 and others are less than 1. This indicates that three factors can be determined from this set of questions that forms the complex variable "Consumer Choice".

Table 5. Factorial Analysis for Consumer Choice

Variable	FACTOR		
	1 Brand Image	2 Information	3 Perception of risk
RI1.1 I can be overcharged by an alternative service provider	-0.105	0.032	0.406
RI1.2 I may not receive the service I expect from another provider	0.066	-0.006	0.354
RI1.3 I think buying the service from another service provider will result in financial loss	-0.007	-0.021	0.363
RI1.4 I am not sure that the signal will be stable with another service provider.	0.063	-0.007	0.343
IN1.1 I ask for advice from others before purchasing internet services.	-0.045	0.423	0.079
IN1.2 I seek to read the opinions of others on the service	-0.050	0.468	0.011
IN1.3 I am interested in reading information on how internet service is provided by other companies	0.112	0.360	-0.108
IN1.4 Information provided via the Internet or at the point of sale is satisfactory	0.312	0.108	-0.048
I1.1 I always had a good impression of my internet provider	0.461	-0.052	0.000
I1.2 I believe that my service provider has a better image than its competitors.	0.440	-0.038	0.034
Eigenvalue	2.486	1.735	1.297
% of Variance	24.861	17.352	12.973

The first Factor with the Eigen value 2.486 covers 24.861% of the total variance. For this factor, we have the highest coefficient values from the group of questions I1.1 and I1.2 that belongs to the independent Corporate Image variables and IN1.4 that belongs to the independent variable Information. This factor will be named "Brand Image".

The second factor with the Eigen value 1.735 covers 17.352% of the total variance. For this factor, we have the largest coefficient values from the group of questions IN1.1 to IN1.3 that belongs to independent information variables. This factor will be named "Information" as it is defined by independent variables of the same name.

The third factor with the Eigen value 1.297 covers 12.973% of the total variance. For this factor we have the highest values of coefficients from the group of questions RI1.1

to RI1.4 that belongs to the independent variables of Perceived Risk. This factor will be named "Perceived Risk" as it is determined by independent variables of the same name. From the matrix, it can be seen that the other coefficients are small and can be neglected.

Table 6. Factor Correlation matrix

Factor	Brand Image	Information	Perception of Risk
Brand Image	1.000	.092	.263
Information	.092	1.000	.067
Perception of Risk	.263	.067	1.000

Table 7 presents the results of the factorial analysis for the reliability of the three factors of customer choice. The overall Cronbach Alfa coefficient is $0.649 > 0.6$ which is the very reliable level according to the Alpha Test Table.

Table 7. Reliability of composite variables

Variable	Correlation Coefficient	Cronbach Alpha by eliminating variable
RI1.1 I can be overcharged by an alternative service provider	0.262	0.636
RI1.2 I may not receive the service I expect from another provider	0.361	0.615
RI1.3 I think buying the service from another service provider will result in financial loss	0.274	0.634
RI1.4 I am not sure that the signal will be stable with another service provider.	0.343	0.618
IN1.1 I ask for advice from others before purchasing internet services.	0.317	0.624
IN1.2 I seek to read the opinions of others on the service	0.283	0.631
IN1.3 I am interested in reading information on how internet service is provided by other companies	0.236	0.640
IN1.4 Information provided via the Internet or at the point of sale is satisfactory	0.308	0.626
I1.1 I always had a good impression of my internet provider	0.371	0.615
I1.2 I believe that my service provider has a better image than its competitors.	0.402	0.608

Table 7 shows that correlation coefficients for all questions are low (less than 0.5). The exclusion of each of the questions does not affect the increase in the value of Cronbach Alfa. The Cronbach Alfa coefficient continues to represent a very reliable level (> 0.6). For these reasons, these factors influence consumer choice.

Pearson's correlation coefficient

Pearson's correlation coefficient (Pearson's r) was used to examine the relationships among the variables. The value of the Pearson correlation ranges from -1 to 1, If $r = -1$ there is a perfectly negative relationship, if $r = 0$ there is no relationship, and if $r = 1$ there is a perfectly positive relationship.

The correlation analysis between independent variables and dependent variables is summarized in Table 8.

Table 8. Analysis of correlation between dependent and independent variables

Independent variable	Dependent variable	Pearson Correlation	Sig (1-tailed)	Level
Perception of Risk		0.252	0.000	0.05
Information	Customer Choice	0.128	0.004	0.05
Corporate Image		0.556	0.000	0.05

From the results can be concluded that:

- There is a very weak correlation between Perceived Risk and Consumer Selection, $r = 0.252$, $p = 0.000$ ($p < 0.05$).
- There is a very weak correlation between Information and Consumer Selection, $r = 0.128$, $p = 0.004$ ($p < 0.05$).
- There is a Medium Correlation between Corporate Image and Consumer Selection, $r = 0.556$, $p = 0.000$ ($p < 0.05$).

Table 9. The Consumer Choice Model - Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics					Durbin-Watson
					R Square Change	F Change	df1	df2	Sig. F Change	
1	.252 ^a	.064	.061	1.33204	.064	28.602	1	421	.000	
2	.272 ^b	.074	.070	1.32609	.011	4.788	1	420	.029	
3	.564 ^c	.318	.313	1.13933	.244	149.979	1	419	.000	1.770

a. Predictors: (Constant), RI b. Predictors: (Constant), RI, IN c. Predictors: (Constant), RI, IN, I;

In Table 9 can be summarized that R^2 (R Square) has values respectively 6.4%, 7.4%, and 31.8%. This indicates that the complex variable Perceived Risk only affects 6.4% in the dependent Choice, whereas the largest influence is from the variables that are not included in the model. The value of R^2 increases to 7.4% when the complex variable Information is added, and 31.8% when the complex variable Image is added. This indicates that the variable "I" significantly improves the model.

Multiple regression model

$$y = \beta_0 + \beta_1 X_{I1} + \beta_2 X_{I2} + \beta_3 X_{IP} + \varepsilon$$

for the dependent variables Consumer choice is given below:

Model 1: $CC = 4.356 + 0.254 \cdot RI + e_{PK}$

Model 2: $CC = 3.885 + 0.243 \cdot RI + 0.106 \cdot IN + e_{PK}$

Model 3: $CC = 2.422 + 0.082 \cdot RI + 0.054 \cdot IN + 0.461 \cdot I + e_{PK}$

Table 10. ANOVA for Customer Choice

Model		Sum of Squares	Df	Mean Square	F	Sig.	F _{kr}
1	Regression	50.750	1	50.750	28.602	.000 ^a	
	Residual	746.993	421	1.774			3.89
	Total	797.743	422				
2	Regression	59.170	2	29.585	16.824	.000 ^b

	Residual	543.891	419	1.298			2.65
	Total	797.743	422				

a. Predictors: (Constant), RI b. Predictors: (Constant), RI, IN c. Predictors: (Constant), RI, IN, I d. Variable Choice

Multiple regression analysis results obtained for the dependent variables Consumer choice and complex variables perceived risk, information and Brand Image are presented in Table 11.

Table 11. Multiple regression between complex variables and Consumer Selection

Variable	Standardized Coefficients Beta	t	Sig.	T _{kr}	Correlations Part
(Constant)		8.730	.0016		
RI	.081	1.913	.076	2.353	
IN	.052	1.282	.145		
I	.523	12.247	.0006		.513

Consumer Choice is expressed as follows:

Model 3: PK = 0.513 * I + ePK

Brand image is the most important variable that influences consumer choice of Internet service providers in Albania.

Conclusions and implications

The key question of the research is to identify the factors that influence the customer choice of ISPs. Based on the literature review there were key factors influencing the customers' decision among ISPs which relevance had to be tested in the Albanian market. The findings indicate that the choice of the customer is primarily influenced by the ISP image. This is supported by many researchers who propose that corporate image should be considered as an intangible asset. Brand image plays a decisive role in the process of choosing ISPs in Albania. Internet service providers should show particular attention to their image as a tool to build a competitive position. There is a common sense among customers that a service provider with a good image will always perform well. Internet providers marketing strategies should focus on integrated marketing

communication strategies such as advertising or public sponsorship, social responsibility to develop brand image and gain an outstanding position in the customer's mind and influence their decision. Also, reinforcing the tangible and intangible benefits of the brands can positively contribute to strengthening their brand image.

Results show that consumer choice is not significantly affected by the level of perceived risk. Albanian consumers do not consider to waste time and effort in choosing the internet service provider. In a collectivist culture, it is thought that the risk is diminished by others' recommendations and company reputation, and no personal effort is sought in collecting, analyzing and comparing information. In the Albanian consumer psychology, the phrase "all are the same" still remains, without making major effort to compare between brands. This can be argued by the information factor and the impact of the amount of information required in the selection.

The factorial analysis and multiple regression analysis explored the relationship between information and consumer choice and indicated that consumer choice is not influenced by the information sought. In Albania, ISPs are concerned more in promotional offers rather than instructing consumers. There is no comparative information on Internet service providers in the country, such as the real speed of the Internet and how much it differs from the contract, how stable the service is, how long is the response time or technical assistance. Regulatory entities and companies do not publish periodic reports with real-time internet monitoring.

Detailed and comparative information from service providers and regulatory authorities would help consumers to have a vision much before making their choice and not just rely on the name of the company.

Albanian customer choice is based on attitude by relying on the general impressions, intuition, and judgment of a brand. Studies show that attitudes are easier to keep in mind than the particular attributes among different brands. Most ISP customer's collect very little information from outside sources before a purchase.

In the telecommunications market there are very small differences between competitors and monetary costs are not considered a factor to switch to another operator. Under these conditions, consumers are guided by the company's good name and its coverage in relation to the price which is perceived at the same level as the internet operators.

Indeed, the corporate image has the potential to influence customer choice and an ISP's competitive standing. ISPs need to work on building corporate value and consistently delivering the high brand experience.

Abstract. *Though recent studies have shown that young adults are highly motivated by extrinsic rewards, the same studies revealed that some of them are less likely to change jobs on account of pay, in certain areas. Millennials are depicted to be highly interested and great consumers of new technology. According to a Romanian study on the grounds of selecting a faculty, the students-subjects have listed as being important, first ranked, the fact that the profile of the faculty must be considered important for the future, followed secondly by attractive courses available and third by the need to be able to take the admission exam in their favorite subject. The methodology is based on an online questionnaire survey applied on students of various profiles from Romania and of various levels, including bachelor, masters, Ph.D. or another high education type of studies. The items analyzed and the indicators chosen to measure them have been analyzed by using SPSS, having also tested the hypotheses with statistical correlations. The findings obtained revealed the fact that Millennial students' degree of satisfaction is quite good as regards the faculty they go to and it strongly correlates with the content of the course. Also, the professors' degree of preparation and training were rated to be the most important to them. Besides, the degree of their satisfaction strongly correlates with the adaption of the study curricula to the current professional needs. As regards the way they choose their faculty, their main focus turned out to be the importance of the field in the future. Referring to the motivation to attend a faculty in Romania, Millennials ranked first the desire to evolve and develop personally and most of them replied that for them, intrinsic gratifications prevail, such as the sentiment of pride, acknowledgment, common mission, professional achievement, finding and exercising their own vocation.*

Keywords: *millennial; motivational landscape; intrinsic motivation; gratification; college; higher education.*

Introduction

While there have been studies performed in Romania on local students' online identity management (Frunzaru & Garbășevschi, 2016) or the use of ICT in students' learning activities (Ivan & Frunzaru, 2014), some others concerning the drive high-school students have when choosing their future educational path (Cismaru, 2013; Frunzaru, Ivan & Pricopie, 2008, 2009; Ivan et al., 2012), yet little focus has been placed on an in-depth depicted motivational landscape of Millennials in Romania when they enter and graduate from college.

Pew Internet and the American Life Project have defined in 2010 the Millennials as being the first generation always connected and have studied the implications of this permanent connection upon education, which put in such a light can itself suffer modifications of its definition, as well as other professions nowadays. Also, the study clearly shows in schematic manners, which are the main differences between the generations, namely:

Millennial	Gen X	Boomer	Silent
1. Technology use (24%)	Technology use (12%)	Work ethic (17%)	WW II, Depression (14%)
2. Music/Pop culture (11%)	Work ethic (11%)	Respectful (14%)	Smarter (13%)
3. Liberal/tolerant (7%)	Conservative/Trad'l (7%)	Values/morals (8%)	Honest (12%)
4. Smarter (6%)	Smarter (6%)	"Baby boomers" (6%)	Work ethic (10%)
5. Clothes (5%)	Respectful (5%)	Smarter (5%)	Values/morals (10%)

Source: Pew Research Center, 2010

Mainly, according to Leung (2004), Millennials are characterized as having the main following characteristics: 1) they prove a global orientation and being emotionally disinhibited, having raised understanding the need of interconnection of a global community, they find it very easy to express their thoughts and feelings online, under the illusion of a certain anonymity; 2) they consider that they are entitled to information and education, they are supporters of a continuous learning process because they know they will have along their lives more jobs or even careers and thus, they want to increase the degree of employability; 3) they are technology specialists, innovative and have a deep investigation spirit, are passionate by the way technology works and they want a world full of unlimited available number of choices; 4) they are preoccupied with maturity and adulthood, wanting to be treated like adults and judged according to their contribution, not to their age (see also Buckley & Doyle, 2016; McGinnis Johnson & S. Ng, 2015).

Having in mind all above depicted aspects, the current paper aims at describing the motivational landscape of Romanian Millennials to enter and graduate a faculty, being state or privately-owned, with a focus on what drives them to strive through all exams and projects to be delivered, how they appreciate the faculty environment, splitting the concept of liking or disliking their faculty (last entered or graduated) in a series of indicators, as to better analyze their opinions and radiate them into a series of conclusions.

The conditions for the answers to be taken into consideration and included in the analysis were the followings: the respondent must be part of the Millennial generation, i.e. be born between 1980 and 2000 and he/she has been a student in a faculty in Romania, state or privately-owned, this quality including all its possible stages, such as a) being a student in progress, b) having graduated the faculty or c) having been a student and leaving the faculty chosen before graduation, no matter the reasons. All respondents not matching the above criteria were deleted from our database.

The Questionnaire was applied in Romanian, according to the native language of the target respondents.

Literature review

A research conducted in the National University of Political Studies and Public Administration, Bucharest, focused on the use of ICT and the study activities of college students (Frunzaru & Ivan, 2014). The results showed that the level of satisfaction of students towards the computer knowledge obtained in the faculty years tends to be low and positively correlated to the number of courses they attended and negatively correlated to their level of expectations (Frunzaru & Ivan, 2014, pp.1-2).

As regards the value system and the behaviors, there is another important study that reveals the deficiencies of the access to and equity in higher education levels (Cismaru, 2013). Studying both students (high-school and university) and teachers, the study shows that high school students place an emphasis on qualities like ambition and intelligence, followed by family unity and education, yet assign very little time to read and study; also, especially in the rural area, they spend a lot of time helping with the house chores. Some students in this last sub-segment have admitted that they were forced to abandon school due to family issues and material problems (Pricopie et al., 2010; Frunzaru et al., 2013, pp.159-160).

A most recent study on failure applied to Millennials as regards study activities reveals very interesting conclusions on their motivational landscape and, better yet, on the impact, their parents' education pattern had on them and on the role a faculty can play to maintain the students engaged and aware that they can overcome any such unaccomplishments. That is to say when a student fails, the educator or the faculty, generally speaking, can help to understand the positive part of that experience, the self-discovery and push them to be better next time. Reframing failure is how they can be helped to understand it and both overcome it. All this put in the context of Millennials having grown educated by "helicopter parents" makes this equation even more complex (Ramirez et al., 2018, p.50).

The concept of "helicopter parents", defining a type of parenting accepted nowadays as rather harmful to the subject-children because of the amount of control exercised on them and the over-protectiveness manifested at all times, mainly depicts an approach in which failure is seen as fully negative, unacceptable, not an option, placing thus a larger pressure on children to always succeed in order to be appreciated. In such a general picture, the idea that the faculty, through its educators, has a very important role in supporting students to grow after each failure and even further, find their true calling in life, promoting personal development, is very interesting. Recognizing anxiety, building trust and commitment, developing healthy relationships, viewing failure as a symptom and normalizing failure represent a set of recommendations that the study authors indicate for the better outcome for both students and society (Ramirez et al., 2018, pp. 54-56). The potential to transform during faculty years anxious students, fearing failure, having self-doubts on their choices, finding it difficult to focus and maintain long-time efforts for the most desired result into emotionally healthy persons, well determined and aware that failure is just a learning opportunity is the key to understanding in fact which is the high role that a college can play in all this process.

Having been at least within the last 15 years under strong analysis by researchers, the Millennials have been observed through different lenses of the microscope. Called either Millennials or Generation Y (Howe & Strauss, 2000), Trophy Kids (Alsop, 2008) – name

derived from the habit of granting a trophy to all kids participating in a competition, no matter the result, Generation 9/11 or Homeland Generation (Horovitz, 2012) revealing the major impact terrorism has had on them, this strip of individuals have been depicted and analyzed both in negative and in positive frames. Thus, while some researches show them as neurotic, anxious and depressed (Twenge, 2000; 2006), others depict them as being ambitious, confident and optimistic (Howe & Strauss, 2000). Clearly, they can be both, different segments or even the same segment in different points in time and moments of their evolution, but the role of education on improving their background, no matter which, is the one worth a real focus (Buskirk-Cohen, Duncan & Levicoff, 2015, p.3).

There are studies that intend to show the important role that parent and family engagements in the college experience have (Kiyama et al., 2015), meaning seeing them as partners in this process of cultivating the right values to the college student and there are other studies focusing on how can library research be fun and on how using games can help nowadays information literacy instruction in higher education (Young, 2016), all trying to identify possible aids in making the college experience better for Millennial generation, aiming not at pleasing them, but yet at the core efficiency of the process.

A recent study on Singapore Millennial students show an important trend through those being at a certain point out of school and later on trying to catch up with their studies in order to learn to be competitive in the workforce market, meet a professional request or enrich themselves intellectually (Chong, Loh & Babu, 2015), all this revealing a new enlarged boundary to this schooling process as one longer than 18 to 24 years of age, thus having to deal with a very diverse profile of the students (from married, single or divorced to full time employees or never having worked and being out of school for some years or just continuing naturally the years of study), fact which makes the education process more complicated and difficult to adjust all such backgrounds (Chong, Loh & Babu, 2015, p.1).

As regards the Millennials perspectives and preferences, it was revealed that first of all they claim a certain approach and behavior from educators, such as care, passion, enthusiasm, communication of clear expectations and duties, courses applicability by matching the information taught with the tests applied eventually, a high desire for real-world examples or models to learn from and applied exercises to practice, i.e. as many active learning opportunities as possible (Dunneback & Therrell, 2015). All the above claims would then turn into their attention and focused improved, as well as the ability to stay engaged also at school and at home for individual study (Dunneback & Therrell, 2015, p.49).

Methodology

The current analysis is testing three hypotheses, namely: H1 – Romanian Millennial students have a low satisfaction degree regarding the faculty attended in Romania, H2 – Romanian Millennial students choose the faculty to attend in Romania mainly according to degree of importance of the field studied in the current society and H3 – The main motivational indicator for them to go to college is to get a higher education diploma.

Around the three hypotheses indicated above, a set of questions were elaborated as to split the items desired to be measured. Thus, there were four parts in the online questionnaire elaborated, with the following structured design:

Table 1. Questionnaire structure design

Part of the questionnaire	Dedicated to	Item
1/4	n.a. (opening questions)	Q1 – Q4
2/4	H1 (RQ1)	Q5 – Q6
	H3 (RQ3)	Q7 – Q10
3/4	H1 (RQ1)	Q11
	H2 (RQ2)	Q12 – Q14
4/4	n.a. (demographics)	Q15 – Q18

The research was run in June 2018 and it gathered a total of 102 responses. After eliminating the respondents who exceeded the age margins (over 38 years of age), 11 in total, and them those not being a student actually (including the uncertain ones, meaning those replying with a simple “No” to the question asking them to name the last faculty attended and/or graduated, which could have been an error of judgment from their part, for the sake of an accurate interpretation), another 5 in total, the number of respondents actually being part of the research remained 86.

Results

For these eligible respondents, ages varied between 19 and 38, and 62 respondents were female (72.09%). In fact, most of them are ranged between 19 and 29, i.e. 74.42%, the rest is up to 38 years of age (25.58%).

Figure 1. Chart with the distribution of all respondents' ages, before due eliminations

Only 12 respondents do not have a job at all, nor attend any internship with any employer, meaning that the vast majority of 86.05% have a job of some kind, be it part-time, full-time, internship or other such programs, or even have more jobs at once (0.1%).

Out of the total respondents under analysis, 51.16% are or were students at the bachelor's degree level, 43.02% at the masters' degree and only 5.82% had Ph.D. studies or others alike, finalized or ongoing. Moreover, only 4.65% are or were students in privately-owned faculties, the vast majority of 95.35% attending a state faculty.

Also, only 3 respondents were from rural areas, meaning that the rest of 83 were from urban areas, Bucharest or other cities in Romania. Bucharest faculties analyzed represented yet the major part, with 72 respondents (83.72%). Having only 11 respondents from other cities in Romania than Bucharest, the results cannot be spread to the entire country surface, thus the study will remain with its core reference to Bucharest students, as described.

Another interesting result is that only 3 respondents out of the 86 eligible (3.49%) have abandoned the faculty they were admitted to, before graduating it.

The experience with the faculty chosen and degree of satisfaction

When asked if they think that the higher education in Romania is going on a good direction or a wrong one, 33.72% replied that the direction was good and 53.49% considered that the direction was wrong.

Yet, as we will see further on, the degree of satisfaction directly related to the faculty attended is quite good, as the mean for Q5 measuring how satisfied they were with the courses conducted so far in their faculties was of 3.08 ($\sigma = 1.01$). As regards the degree of satisfaction related to other several indicators revealing their overall faculty experience (Q6), the segment that brings them the greatest satisfaction resulted to be the relation with their faculty colleagues.

Correlating the item measuring the overall degree of satisfaction towards the courses they had so far (Q5) with the item revealing their overall faculty experience (Q6), it clearly resulted that their degree of satisfaction strongly correlates with the content of the course ($r = 0.62$), with their relationship with the professors ($r = 0.57$) and thirdly, with the courses schedule ($r = 0.55$).

RQ1							
	Q5. How satisfied are you, in general (1 – very unsatisfied, 5 – very satisfied), with the courses conducted so far in your faculty?	Q6. How satisfied are you as regards (5 – very satisfied, 1 – very unsatisfied): Your relation with your faculty colleagues?	Q6. [...] Your relation with your professors?	Q6. [...] Your relation with the faculty personnel (secretaries, etc.)?	Q6. [...] The courses schedule?	Q6. [...] The courses content?	Q6. [...] The faculty building and the course rooms?
Average	3,08	3,93	3,58	3,23	3,64	3,30	3,51
St. Dev.	1,01	0,90	0,96	0,97	0,97	1,04	1,23
Pearson Correlation		0,19	0,57	0,28	0,55	0,62	0,23

Figure 2. Correlation between the overall satisfaction degree towards the courses and items revealing the faculty experience

Moreover, the current and/or former students were asked to rate from 1 – very weak to 5 – very good a series of items constructing the faculty experience they had so far, among which the professors' degree of preparation and training, the interactivity of the courses and seminars, the courses quality, both theoretically and practically, the use of new technologies in the courses, the adaption of the study curricula to the current professional needs, the support and guidance provided to students, partnerships between the faculty and employers in the market to hire students (part-time, full-time,

internship, etc.) and the modernity and equipment of the faculty building and courses rooms.

The professors' degree of preparation and training was rated to be the most important to them, followed by the quality of the course at the theoretical level, the interactivity engaged in courses and seminars and the support and guidance provided to students during the faculty years. Unexpectedly, the use of new technologies only ranked sixth in this top.

Yet, correlated with the item measuring the overall satisfaction degree (Q5), it resulted that their degree of satisfaction strongly correlates with the adaption of the study curricula to the current professional needs ($r = 0.61$) and with the quality of the course at the theoretical level ($r = 0.54$).

RQ1										
	Q5. How satisfied are you, in general (1 – very unsatisfied, 5 – very satisfied), with the courses conducted so far in your faculty?	Q11. In your opinion, in the faculty you attend now or you last graduated, the following aspects were rated as follows (1 - very weak, 5 - very good): The professors' preparation and training	Q11. [...] The interactivity in courses and seminars	Q11. [...] The courses quality (at the theoretical level)	Q11. [...] The courses quality (at the applied level)	Q11. [...] The use of new technologies in courses	Q11. [...] The adaptation of the study curricula to the current professional needs	Q11. [...] The support and guidance provided to students	Q11. [...] Partnerships with employers in the market to hire students (part-time, full-time, internship, etc.)	Q11. [...] The modernity and equipment of the faculty building and courses rooms
Average	3,08	3,91	3,43	3,70	3,02	2,80	2,87	3,26	2,71	3,07
St. Dev.	1,01	0,88	1,20	0,99	1,18	1,24	1,17	1,20	1,30	1,39
Pearson Correlation		0,47	0,50	0,54	0,42	0,50	0,61	0,50	0,40	0,37

Figure 3. Correlation between the overall satisfaction degree towards other courses and items revealing the faculty experience

Observing figures 2 and 3 above, one can understand the main indicators that are important to Millennial students (current or former) are the quality of the courses and their content adapted to the current market needs, the relation with the professors and also the timetable they have to insert into their programs, maybe because, as seen in the introductory part of our analysis above, most of them are already working.

Criteria of faculty choice

But how did Millennials choose their faculty initially? According to the data recorded, their main focus was on the importance of the field in the future. Thus, a significant pragmatic factor is involved in their selection process, a factor which is already agreed to be part of the Millennial matrix. Also, the curricula must attract them, because Millennials rarely do things they do not like. Moreover, the fame and reputation of the faculty and of the professors teaching there are also important to Millennials when choosing where to study after high-school (Frunzaru, Ivan & Pricopie, 2008).

Millennials do not pay so much attention to the admission exam, whether it is just a file with registration documents or a specific exam to be taken, nor are they focus to choose a faculty where they should study as little as possible, where the demands to pass are low, so that their efforts would be as low as possible.

RQ2						
Q12. How important (1 – not important at all, 5 – extremely important) are the criteria below in your opinion when deciding to attend a specific faculty?						
Q12. [...] Choosing a field of importance in the future	Q12. [...] Choosing a very attractive study curricula	Q12. [...] Choosing a faculty where the admission exam is taken at my favourite subject/s	Q12. [...] Choosing a faculty where the admission is based on a registration file, without an actual admission exam	Q12. [...] Choosing a famous faculty, well-known professors and exceptional results	Q12. [...] Choosing a faculty as non-demanding as possible for students	
<i>Average</i>	3,95	3,85	3,23	2,12	3,49	2,19
<i>St. Dev.</i>	0,91	0,82	1,04	1,20	1,26	1,09

Figure 4. The choice criteria involved in choosing a specific faculty

The motivation for attending a faculty in Romania

In the last section of our research, it was intended to lay a closer look at the motivational landscape that Millennials inhabit. What keeps them going through the faculty years and why they study and pass exams, and finally graduate? As seen above, only 3% abandoned faculty, this meaning that most of them, after selecting their faculty according to their criteria, justify their admission efforts further on and continue to study and accomplish the mission they took on initially.

Asked why they took an admission exam to a faculty in the first place, Millennials ranked first in their motivational landscape the desire to evolve and develop personally, followed by the intention to study what they like and to become specialized in that field and also, again the pragmatism feature arising, to have a well-paid job in the future. For them, it is not so important to just obtain a diploma, neither to relate to youths with the same interests as them (professional networking) nor to please their parents. Millennials are no longer those kids in previous generations who followed a study path imposed by their parents' judgments rather than following their own inner wishes and dreams.

RQ3						
Q7. Which was your motivation to seat for a faculty admission exam? On a scale from 1 (not important at all) to 5 (extremely important), please note the variants below, according to the importance they hold for you.						
	To obtain a higher education degree	To evolve and develop personally	To study what I like and specialize	To relate to other youths same interests (networking)	To have in the future a well-paid job	To please the parents
<i>Average</i>	3,57	4,08	3,93	3,01	3,84	2,33
<i>St. Dev.</i>	1,10	0,98	1,08	1,09	1,13	1,32

Figure 5. The motivation radiography related to seating for a faculty admission (self-evaluation)

But how do they evaluate the same motivational landscape for their generation peers? When asked to answer to the same question as above, but applied to their colleagues and friends, Millennials believe that for the others the desire to have a well-paid job and to get a diploma are the most important, followed by the desire to evolve and develop personally and the desire to study what they like and get specialized in that field. Millennials appreciate that for their generation peers the networking with youths having a similar interest is not so important and neither the desire to please the parents, which remains a feature applicable both to respondents involved and to their peers.

Figure 6. The motivation radiography related to seating for a faculty admission (group-evaluation)

Also, it was our intention to see what kind of gratifications or rewards are mostly in their focus, intrinsic or extrinsic. According to the scores obtained, most of Millennials participating to this study replied that for them, intrinsic gratifications prevail, such as the sentiment of pride, acknowledgment, common mission, professional achievement, finding and exercising their own vocation.

Figure 7. The type of rewards that prevail (self-evaluation)

As regards their generation peers, the answers indicated that for the others in their groups of colleagues and friends, they find that the most important gratifications are those of an extrinsic nature, in opposition with their own views. Obviously, a degree of desirability could bias the answers to this group of question, a fact which could be further researched in a new study.

Figure 8. The type of rewards that prevail (group-evaluation)

Conclusions and implications

As shown by the data gathered, when talking about higher education degrees, Millennials are motivated mostly by the quality of both the courses and of the professors. Either is it about the training and expertise or about the kind and depth of relationship they develop together, Millennials appreciate more than anything real guidance, experience, and knowledge, but also a warm relation with those in charge with that education they seek. Thus, it is only true capable and well-prepared professors that will keep them in school, this main idea revealing a most important point to keep in mind for any future education plans or reforms at the level of our country.

Though they answered at the first question opening the survey that the higher education system in Romania is going in a wrong direction, Millennials participating in our survey stated they were quite satisfied with the courses attended so far. As regards their general experience with the faculty attended and/or graduated, Millennial students were mostly satisfied with their relationships with their colleagues and with the courses schedule, which, most probably, allows them also to work, since we have seen that most of them already have a job.

Moreover, for them, the degree of preparation and training, the real expertise of the professors, as well as the quality of the courses are ranked first, so this means that they have high expectations from a faculty, once they chose to attend it. They want quality above all, but also warmth, guidance and, why not, leadership and mentorship.

When choosing the faculty, the Millennials first make sure that the field they will study has a significant importance in the future. Being important, it somehow also results that those jobs will be well paid. Also related to this, the study curricula must be attractive,

because it is well known that they get bored very fast, they need to be gained and kept engaged throughout the study years by means of quality and attractiveness.

As regards the motivation, the drive they have when studying in a faculty, Millennials clearly stated that their main focus is to evolve and develop personally, followed by the desire to learn more in the subject they prefer and to be able to get afterward a well-paid job in the market.

In opposition to these answers, their opinion about their peers' motivation is a little reversed, meaning that they feel that their colleagues and friends in the same generation are focused on getting a well-paid job and a diploma more. So, the main vision about themselves is that they aim at more immaterial, personal, vocational objectives, while the others only, not them, are more pragmatic and materialistic.

This last discovery is also verified by the fact that when asked about what prevails for them in general, as regards the study activity, the intrinsic rewards or the extrinsic ones, they do the same switch of mirrors, and again they state that they respond and focus more on intrinsic gratifications (finding their true calling and vocation, having a common mission, feeling accomplished, etc.), yet their generation peers respond more and better to extrinsic gratifications (material ones, bonuses, benefits, etc.).

As regards the three hypotheses tested by the current research, we have only one confirmed (H2), namely that regarding the college choice patters. Find here below the general overview:

No.	Hypothesis	Expectation	Result	Confirmed?
H1	<i>Degree of satisfaction on the college attended</i>	Low	"Quite good" (38.2%)	NO
H2	<i>College choice pattern</i>	Studied field importance degree	Studied field importance degree	YES
H3	<i>Motivation to go to college</i>	To get a diploma	To evolve personally (personal development)	NO

Figure 9. General overview of the hypotheses tested

The limitations of the current research could stem from the particularity of the sample, namely from the fact that most of the respondents were residing in Bucharest (78.4%) and most of them were female (69.6%), thus the results recorded could mostly represent a radiography of women living in the capital city of Romania and could not be extended at the level of the entire country.

Yet, the implications resulted from this study must be taken very seriously since we should all focus on a better education system in general in this country. The current study results must be related to the reality of our current society. It is not meant to keep the conclusions reached an idealistic level, nor to abandon them because they may be hard or even impossible to implement in faculties across Romania, yet we consider that they should at least be kept in all educators in higher education systems fierce focus as to come to them as close as possible, as the current social and political trends allows them.

It is the only way in which, by processing the feedbacks from our students, the universities can improve their services – as ultimately, this is what they are, service providers to citizens and society in general – and meet the real needs and requirements imposed not only by this new generation, Millennials, which is the current largest workforce population worldwide as compared to previous generations but by the features of our current lifestyle and degree of development as a society, as a whole.

The faculties' mission to meet their education targets towards the beneficiaries must not be forgotten, nor abandoned, no matter the hardships or obstacles met on the way. The ideal must keep its place in our minds and function as a compass to guide all our actions, day by day, course by course, project by project.

Our further set of recommendations is to support as much as possible the professors to keep training and learning about the latest discoveries in their field, on the one hand, and encourage students to learn by granting them as many scholarships as possible, on the other hand. The real support towards students in their everyday life hardships, including finding a decent job, should not be overlooked. And last, but not least, the teaching methods and the curricula must be, no matter the field taught, passed through the filter of the new technologies and dressed into modern clothes for the students to be able to better digest the new information and see it, keep it and perceive it like a real, big, important benefit that has a concrete, positive impact on his/her life.

In other words, professors individually and faculties as an organization should always measure their results and see if the activities they run, the classes they teach and the projects they coordinate really have the desired quality and impact and always adjust the objectives and the measurements next time, so that constant improvement of the education process and permanent contact with the students remain always in full emphasis.

Abstract. *The future means cutting-edge technology, much more developed human relationships, but lacking effective engagement, advanced knowledge and also new frontiers to achieve. Thus, the society of the future means technology, unlimited possibilities of unknown connections and challenges. All these opportunities are, however, associated with risks, threats and vulnerabilities. The Internet, as a tool, has significantly contributed to the technological and scientific progress of mankind. The multitude of opportunities it offers and easy access to every citizen, with the lack of a unitary legislative framework at an international level, effective and concrete control over the development of some applications. This confrontation does not always have the desired result, and the relatively controlled development and use of it is very difficult to achieve, especially for state actors. The virtual world thus gains ground through addiction, the cyberspace becoming the quirk that aligns the successes and failures of mankind, the pattern of future battles that can reconfigure the map of the world, the easel on which our deep emotions are outlined. It is a mirror of society and the place where predictions on the future can be sold. Cyberspace has no borders. It is globalization in its purest form, it is a new paradigm of modernity. It is the opening of man to man at every level. Risk is a constant component of technological, social and economic development, but knowing the limits in which it can manifest, through its anticipation and action can diminish its negative effects. In front of the cyber-attacks, everything becomes vulnerable - from the critical infrastructure of a country to the security of each individual. The product effect is chained, each vulnerability creating prerequisites for exponential growth of associated risk and affecting security from an individual level to a global level. The virtual world is already the world of tomorrow. How will we identify the opportunities and manage the benefits? And how will we reduce the associated risks, current and future threats? What are the solutions? These are the questions we will be trying to answer through our study. For this purpose, the current situation of the Romanian society connected with the transformations brought by the cyberspace will be analyzed. We will refer to the infinite possibilities of action, information resources and products in operation, and we will try to identify effective actions that can limit the risks.*

Keywords: *Digital transformation; Cyberspace; Treats; Opportunities; Risk management.*

Introduction

Cyber space has been called the fastest technological space of evolution in human history, both in scale and in terms of properties, the "fifth theater of operations" as Marc Goodman called it. Citizens have the right to exteriorize, in the virtual space, their emotions, thoughts, creations without being constrained in any way: such as, expression, content, and form. This freedom generates new issues, especially legal controversies, that way imposing a substantive reorientation in the interpretation of freedom of expression. The extensive community of Internet users, the ones with easy access to virtual environments, generate a rich palette of cultural patterns, way of thinking, preferences, habits, necessities and, implicitly, generates a demand for extremely varied contents (Buzan, 2014).

This information must be available instantly and, most often free of charge, in this way the information market is constantly growing, by demanding and offering more complex virtual services. Throughout this virtual world, the sense of security is given by the anonymity, even if only to a relative degree.

Under the protection of anonymity, you can request data, information, and you can convey opinions and messages, without being subjected to legal treatment or sanction. This stimulates the courage to ask and convey information. In this "legal paradise", users are banned from legal constraints, which generates a detachment behavior towards the rules applicable to ethical conduct in the virtual space and a comfortable, intimate state in this global community.

The relative security offered by anonymity in virtual space, as well as the large number of smart devices or applications designed to simplify our lives, turn us into potential victims of hackers. It is impossible to have total, effective protection against these kind of attacks in the virtual space. Marc Goodman believes that "all personal data disseminated online or offered by accepting the terms of use of applications transform us from customers to products". The target of these attacks is the information, the data that can be obtained, and the costs that generate the development of applications that can generate data are insignificant in relation to the profits made by the experts who develop them.

New economy or the digital economy

The digital economy is defined as being the interaction between the personal computer, the Internet, telecommunications and electronics, having a set of distinctive features towards the traditional economy.

The new business model - e-business, e-commerce, e-banking, etc. - developed via the Internet, brings a radical change in efficiency: costs, including transaction costs, are reduced, based on the business/business relationship (B2B), business/customer (B2C), C2B and C2C business/employee (B2E) business/government (B2G), government/business (G2B), etc. This ecommerce model has developed exponentially in the last decade, and has expanded into all areas, now being considered the concrete form of accomplishing most businesses (Gordon, 2016).

The microeconomic and macroeconomic effects of the new economy and information systems are based on the generally valid principles of its development, which are: awareness, accessibility, availability, affordability and appropriateness.

Electronic commerce

The figures and statistics put into place by the main players in the Romanian electronic commerce show that in 2017, online shopping grew to 2.8 billion euros, 40% more than in 2016 with a registered 1.8-2 billion euros. This would mean that Romanians spent an average of 7.67 million euros every day of the year on internet shopping (details on e-commerce in Romania in Zbucea, Vătămănescu & Pînzaru, 2015).

This value refers strictly to e-tail, without considering services, utility payments, airline tickets or holidays, hotels, shows reservations. The 40% increase is one of the highest in the EU countries, but rather small compared to the developed economies, thus showing the enormous potential for growth in this segment.

Figure. 1. Global market with the highest online shopping penetration rate as of 2nd quarter of 2017 (Source: Processing after <https://www.statista.com/statistics/274251/retail-site-penetration-across-markets/>. GlobalWebIndex ©Statista 2018 Additional information: Worldwide, GlobalWebIndex; Q2 2017, 16 to 64 years)

E-commerce is a concept that designates the process of buying and selling or exchanging products, services and information, using a computer network, including the Internet. This concept can be defined from several perspectives: communications, business processes, services, or online. The used technologies are diverse, including messaging, internet, and intranet or extranet services.

The reasons for the implementation and development of e-commerce are based on the ongoing need to broaden the clientele, as well as to reduce the costs for services and distribution towards customers. The initiation costs of an electronic commerce process are quickly amortized, with the main advantages being the volume of information sent through the electronic channels, the upgrading and accuracy of the transmitted data, as well as a better control over the market segment to which the message is transmitted. Back-up can be received in real-time, changes required by the market or development

policy can be applied or modified immediately. Other benefits of using e-commerce are: interoperability, global character and easy to use.

According to **Statista**, global retail e-commerce sales will reach \$ 4.5 trillion by 2021 (246% more than 2014).

Figure 2. Worldwide digital buyers versus Retail e-commerce, 2014 to 2021

(Source: Processed data eMarketer ©Statista 2018)

<https://www.statista.com/statistics/251666/number-of-digital-buyers-worldwide/>

<https://www.statista.com/statistics/379046/worldwide-retail-e-commerce-sales/>

Financial-banking activities

The development of the banking market also took into account digital technologies. Banking systems are being used more and more, whether it be credit, cards, ATM or POS. The client is virtually positioned within the banking institution through mobile, internet and home banking. The development of these systems was also possible due to the explosive development of digital telecommunication, the advanced technology installed on mobile phones (Grigorescu, Chitescu & Diaconeasa, 2016).

However, in this situation, the risk of using electronic banking services on smart devices increases due to the dual way of achieving the security of these operations: both banks and mobile phone operators must develop encryption systems for transmitted data as well as secure reception channels or data transmission. It is necessary to establish common security, interoperability and compatibility parameters of the offered services.

Socialization – social media

The presence of e-commerce on social media networks has become a must-have, regardless of the type of business: B2B or B2C. Being the space where more and more people spend their free time, the social media approach from the perspective of electronic commerce is essential. It is a familiar environment where you can learn or realize the value of a product or service. Studies have shown that more and more social media consumers are looking for product reviews on their favorite social network, and in this way they can decide the degree of trust they have for that brand.

It is the social-proof effect - when a social networking user gains confidence in a brand based on reviews received from virtual friends - influencers. Promoting a product on social networking is more applied, these networks identifying a certain type of behavior and consequently, adapting the promotion to that profile. The tools offered by these social networks also allow the measurement of trade efficiency of this type.

According to Statista, 80% of people frequently accessing social networks are shopping online, and 50% often shop. 71% buy products only based on reviews in the virtual space or based on recommendations.

Figure 3. Online shopping penetration rate vs. Time spent on the internet
 (Source: Processing after <https://www.statista.com/statistics/274251/retail-site-penetration-across-markets/>. GlobalWebIndex ©Statista 2018 Additional information: Worldwide, GlobalWebIndex; Q2 2017, 16 to 64 years)

In figure 3 we analyzed the penetration rate of online shopping in different countries, relative to the average time spent by users in those countries on the Internet. The percentage of time spent on the internet was calculated as the ratio of time actually spent in 24 hours. Regarding that in those 24 hours a person has different activities - sleep, meals, work/school, etc. - we notice that the time allocated to the virtual space is very high. Thus, in Thailand, the time spent on the internet exceeds 9 hours a day.

The dynamics of the increase in the use of information to and from the virtual space shows that the number of users increases daily by more than one million. In 2018, the total number of users is over 4,021 billion, up 7% from 2017. The number of social media users is almost 3,2 billion, up 13% from 2017, as we have over 5,135 billion mobile phone users. GlobalWebIndex shows that, on average, an internet user spends about 6 hours a day using Internet-based devices and services. If we evaluate this time at the level of over 4 billion Internet users, we see that in 2018 alone, over one million years, cumulated, will be spent on the internet.

The processing of the data in figure 3 shows that developing countries have, in relation to the value of online shopping, a long time spent on the internet. This is explained by

the fact that these countries have been introduced to technological developments in recent years, the internet being a much newer tool than in developed countries. Emphasis is placed on capturing information, on social media with its advantages and disadvantages. In African countries like Mali, the number of social media platform users increased 6 times in 2017. Accelerating access to these economies will influence Internet experience for users everywhere, companies such as Facebook, Google, and Alibaba will have to adapt their resources to deliver products that meet the needs and demands of these emerging economies.

Risks in cyberspace

The dynamics of virtual space expansion and its intersection with social relationships in the real world are genuine challenges (Dunnigan, 2010). Vulnerabilities and risks tend to arise. **Vulnerability** is a weakness of a hardware or software system that allows unauthorized users to gain access to it.

The main vulnerabilities in computer systems are physical, hardware, software or human. Information systems are primarily vulnerable to classical attacks when a hacker manages to physically penetrate computing systems and evade confidential information. Every computer system has vulnerabilities, so we can say there is no 100% secure system, an attacker can act in many different ways. Ways of responding to these attacks generate, first and foremost, long time resources: identification of the aggressor, vulnerability and threat analysis, methods used, development of response elements, and counterattacks are necessary.

The dynamics of this field's development requires an equally dynamic evaluation and development of Cyber Security policies, the challenge addressed to specialists in cyber security methods/actions being to reduce the extent of damage that can be produced in the short or long term. A cybernetic attack may have a major impact, may affect the economies of some countries, influence policy decisions, or make decisions in adopting a concrete response. Thus, the solution is a continuous, dynamic technical, analytical and intelligent process that integrates the information provided by various specialized sources (Marga, 2017). It is a process that requires at least the same determination, intelligence and thoroughness that attackers have when they aim to gain access to a targeted cyber infrastructure. The solution has a continuous character, an incomplete and sporadic approach produces a gap between the operational and informational needs, leaving valuable assets under the incidence of the **risk**.

The fundamental role in preventing and combating risks and threats towards national security in all areas of manifestation is held by the state through its defense policies. The main feature of the virtual space - the lack of borders - imposes a more active role, an involvement of all its institutions in the prevention of virtual space threats. The overall objectives of cyber security are to identify and classify the vulnerabilities and risks present in the cybernetic environment, to analyze the evolution and structure of cyber-attacks, to identify good practices on preventing and limiting the effects of these attacks, to research the state preparedness, to counter the risks and challenges present in cyberspace and to analyze the cooperation between the public and private sectors.

Cyber security means different things for different stakeholders, often without a total and common understanding of meaning, implementation and risks (Goodman, 2016).

There are also important cultural impediments, not only between sectors, but also within the same sector or within certain organizations. Traditional approaches to security may be inadequate in cyberspace, but the consensus on alternatives has been elusive.

In the field of intelligence paradigm shifts have emerged - from "need to know" to "need to share" and then "need to share capabilities" - which implies overcoming the formal barriers in the exchange of classified information, the framework of public-private partnerships, in order to effectively improve the communication between the two parties and a unitary and efficient coordination.

Increasing the vulnerability of personal systems to cyber-attacks of any kind is directly proportional to the ability to evaluate the data received by each user. Thus, the more we believe in the screen, the more automatic data will be taken, we will consider them real, without a concrete analysis of them, and without considering piracy of data or sources. Efficiency of an IT system should take into account a set of factors such as the value that needs to be defended, identifying attacks and cyber attackers, or analyzing the attack and finding ways to stop or reduce its effects. A first step in making an answer more efficient takes into account the fact that no system is invincible, that we must change the paradigm of the "non-breaking wall" assuming, the awareness that cyber-infrastructures are already penetrated, that there is no total protection. Attackers are interested in penetrating the informational infrastructure to either detect it for as long as possible in order to access as much filtered information as possible.

The global expansion of cyberspace has led to the development/modification of conflict zones and of modalities of action. Thus, the costs of a cyber-attack have made it possible to attack state-level targets with advanced technological levels, even by traditional criminal groups, but without advanced capabilities, but by using tools that exist on the relevant markets. Goodman said that *"Traditional criminal groups have set up cybercrime divisions to exploit the possibility of huge gains and low risks"*.

This context denounces increased efforts by states to collaborate and coordinate cyber-attacks in partnership with international organizations. It is aware of the need to adopt rules for the use of virtual space, standards for assuming responsibilities in the case of cyber-attacks, and practices in the fight against cyber-bullying committed by non-state actors.

To this end, the United States of America (USA) are an active participant in United Nations (UN) meetings in the field, developing cooperation plans with other states to ensure cyber security (v. Council on Foreign Relations, Cyber Threats and International Cooperation, Workshop Summary Report, Washington DC, 26.02.2015). EU policy places cyber security responsibilities on the prerogatives of member states.

Attributable to this the *EU Strategy on Cyber Security* has been developed, *"representing the EU's global vision on the best ways to prevent and manage cyber-disruptions and attacks"* ("Cyber security issue in international organizations and involvement of Romania as a member thereof", www.mae.ro). This document, even if it does not require a unitary approach at the level of the union, states the collaboration with international partners, the private sector and civil society. A key objective is *"to establish a coherent international policy of the European Union on cybernetic space and to promote the*

fundamental values of the EU" and an implementation measure of "international cooperation on cyberspace".

The states, on behalf of a subsidiarity, can control only 10-15% of the cyber space, the rest being in the private and family sphere, a global partnership approach is needed for the first time with a common mission (Rohrig & Smeaton, 2018), clearly defined objectives and globally accepted, firm action directions and generally valid legal provisions.

According to Marc Goodman, in "Future Crimes", which appeared in 2015 (translated in Romanian in 2016 under the title "X-Cyber: The future begins today"), believes that "we entered the era of computing transformed into a weapon, virtually anyone who has a few dollars to spend can have access to levels of unimaginable cyber power" so far and the action to counter these attacks has to be done voluntarily by every internet user using crowdsourcing strategies ("the action to direct a task to a vast and undefined group of people through a public appeal"), gamming, a "new field of study that allows playful thinking and mechanics in real contexts to motivate and engage players in solving problems concrete" or even improving the public-private partnership.

In 2013, Romania had implemented, the *Cyber Security Strategy of Romania*, whose main directions of action are: *"to conclude international cooperation agreements to improve the response capability of major cyber-attacks; participating in international programs that target cyber security; promoting the national interests of cyber security in the international cooperation formats of which Romania is part of"* (Decision No. 271/2013 for the approval of the Cyber Security Strategy of Romania and the National Action Plan on the Implementation of the National Cyber Security System, Annex no. 1).

Frauds, thefts

According to the Nilsen Report, one of the biggest fears in the online space is fraud. According to this study, in the last 4 years, fraud has developed faster than e-commerce, for every 100 \$ profit, 5.65 cents are stolen. Among the most used methods of fraud, Worldpay has identified identity theft - 71%, phishing - 66%, account theft - 66%, friendly fraud, clean fraud, subsidiary fraud, triangular fraud and trader fraud.

According to CERT.ro, in Romania, in 2015, a number of 2,321,931 IP addresses, representing 26% of the total number of IP addresses valid nationally, were involved in at least one cyber-security alert, and a number of 17,088 .ro domains (6.5% of all .ro active domains) were reported as compromised - up 58% over the previous year.

Manipulation

According to the Sociology Dictionary, *"manipulation represents the action of determining a social actor (person, group, etc.) to think and act in a way that is compatible with the interests of the initiator and not his interests, using techniques such as persuasion that deliberately distorts the truth, leaving the impression of freedom of thought and decision"*. On social networks, manipulation means imposing the interests of some groups by misleading, distorting information, or influencing opinions and behavior of an individual or a group. Manipulation can take many forms: misinformation, intoxication, lies, rumors, persuasion, temporal distortion, attribution, etc.

Manipulation, as a form of deviation from objective information, and plays an active role in influencing the social network user in determining choices, behaviors, action or inaction. In this way, the digital economy becomes a tactical field for professionals in handling. The risk of using the Internet is the presence of disinformation professionals, especially on new media channels, the stake being the large number of consumers of this type of information and their concern for a particular topic (Iancu, 2010). Political manipulation has the greatest impact, by imposing new media as an alternative/competitive form of written media, by eliminating divergences of interest and extending targets.

Terrorism

The most aggressive form that relies on social media networks is terrorism. Terrorist organizations have thus found a way of developing, several main directions: intimidation - by presenting executions or attributing terrorist attacks, in order to create a sense of insecurity - coordination, positioning - by exemplifying the activity that it does - or recruit it. Beyond the social media communication aspects that terrorists use in their work, another extremely violent side of their work is cybernetic terrorism, meaning the use of cybernetic tools for attacks on private or public targets. (Grigorescu, & Chitescu, 2017).

More and more extensive Internet facilities allow the use – without much knowledge- of a "dark net" part of the encrypted Internet, which is not registered by search engines, and which offers a higher degree of anonymity to its users. In this way, tools that help cybercrime develop very quickly and can create state-of-the-art security breaches. Twitter social network closed over a quarter of a million accounts linked to jihadists from the Islamic State, Europol estimates there are no fewer than 90 different platforms and social networks currently used by the State of Islam.

All these negative, harmful, secondary effects of electronic services are not able to determine approaches that restrict the rights and freedoms that cyberspace are offering. There would be a situation in which people interacting in the virtual environment would benefit from different legal protection than those in the real world. Extremely dynamic technology development leads to extremely complicated legal issues (Radziwill, 2015), a natural situation in this context.

The censorship of content handled in the electronic space must take into account the cultural, social, political and economic differences of a user community in a globalized context. Globally accepted legal rules will be established with great difficulty, by identifying and accepting moral norms that each state promotes. In this context, well-defined democracies will better understand the positive valences of the virtual environment, access to vast information resources in all fields - science, education, culture -, and will not lift legal barriers in the cyberspace. Censorship in this environment will be directed to information users/receivers rather than to information issuers.

Cambridge Analytica Case study

An extremely important opportunity offered by virtual space is that it creates a space for debates, opinions of any kind, as well as components of a stable democratic process.

This facilitates the participation of a large number of users in the debates of political ideas and the adoption of certain political decisions on different levels. This type of debate allowed the possibility for low costs in relation to the number of present users, sent messages, the rational arguments presented and the interaction with the other participants in the debate. The reverse of this type of meeting consists in the possibility of manipulating the data of interested organizations for political purposes. Goodman thinks we are now entering "the computer scientist turned into a weapon era".

One of the most recent examples of virtual data security was that of Cambridge Analytica. It has illegally accessed the data of 2.7 million Facebook users in the countries of the European Union. The European Commission said that *"Facebook has confirmed that the data of up to 2.7 million Europeans - or, more specifically, people in the EU - were probably inadequately accessed by Cambridge Analytica"*. Statistically there were 1,079,031 people in the UK, 309,815 people in Germany, over 6,000 Maltese people, 214,134 people in Italy, 211,667 people in France, 136,985 people in Spain and 112,421 people in Romania, 89,373 users in the Netherlands, in Portugal 63,080, 60,957 people in Belgium, 59,480 people in Greece. In Poland, 57,138 people are affected, 55,337 in Sweden, 44,702 in Ireland, and 41,820 in Denmark. In Bulgaria, 35,718 people were accessed, 33,568 users in Austria and 32,067 people in Hungary and 29,376 in the Czech Republic, 21,517 in Croatia, 19,693 in Finland, 15,123 in Lithuania, in Slovakia 14,846, in Slovenia 11,255, in the Republic of Cyprus 7,455, Estonia 5,510, Latvia 4,757 and 2,645 people in Luxembourg.

Figure 4. Country distribution on affected people
(Source: Facebook)

The consultancy firm has thus taken advantage of the vulnerability of data protection in the virtual environment, in this case on a high-impact social networking site, to steal Facebook accounts for use for undeclared purposes, in political interest, with serious repercussions in real life.

In 2014, the company, by interpreting data extracted from social accounts, achieved the political profile of American voters to whom election was influenced by sending personalized political ads. An observer mentioned: *"we have exploited Facebook to get millions of voters' profiles. (...) This was the basis on which the company was built"*. The information was collected through an application called "thisisyourdigitallife" created by Professor Aleksandr Kogan independently of his Cambridge University work, which, through his company, Global Science Research (GSR), in collaboration with Cambridge

Analytica, has contacted hundreds of thousands of Facebook users to complete personality tests under the pretext of using data for academic studies. However, the application also collects the data from the "friends" lists of those who accepted the tests, so the profiles of tens of millions of people have been obtained.

Cambridge Analytica was involved in US President Donald Trump's campaign and the pro-Brexit campaign, that is, Britain's out of the European Union. Named by Steve Bannon as a *"psychological war tool"*, the company exploited Facebook data of tens of millions of American citizens, for electoral purposes, using their Facebook profiles fraudulently to build a powerful software program to anticipate and influence electoral preferences. Facebook Vice President said *"it's a scam. We'll take all the necessary steps to erase the stolen data, we'll initiate legal actions against the authors of the illegal activities"*, Facebook initially did not warn users and took only limited measures to secure data over 50 million people. According to The New York Times, copies of Cambridge Analytica data are still online.

Facebook defended their actions, claiming that *"Most users gave the app access to information such as their public profile, but also the pages they liked, the friends list, and the birthday. It was the same for friends whose settings allowed sharing"* and that it is *"important to remember that bank account details, credit card information, or national identity card numbers have been distributed were not distributed"*, and *"the developer of the application involved in this leakage sold Cambridge Analytica data US users, not users in the EU"*. Facebook will not pay compensation to the 2.7 million European users whose data were improperly transferred to Cambridge Analytica.

Following the scandal, Facebook's CEO, Mark Zuckerberg, apologized for his company's mistakes for using personal data, and assured that he is committed to making changes to that. However, mistrust, suspicion and uncertainty among users did not lead to the creation of an individual culture of information security, meaning the lesson was perhaps only the first step in the informational war.

Figure 5. People affected inside the EU regarding the number of Facebook users and population (Source: Facebook)

In figure 5 we highlighted the percentage of users affected directly compared to the total number of persons in the country. We can observe that there is a balance between these

two values in almost all the EU countries. Therefore, there were no countries regarded as direct targets of this data theft, but it was only the clear tendency to obtain data from as many Facebook users as possible. This is more worrisome because we can observe the global dimension of this attack. The possibility of an economic, social, political manipulation or even a security attack would have regarded as a whole and not a particular case. The effects would have been felt at the EU level as well as globally. Not a country or community was the target, but the extended community of Facebook users, which represents more than 2.23 billion people. At a European level, nearly 3 million people have been affected.

Conclusions

The Cambridge Analytica case is one of the events that has affected a huge number of users and which, thanks to the measures taken by the affected states, have become extremely visible. Similar cases, of a greater or lesser magnitude, but which have not been discovered or have not caused a response of such intensity exist and will still exist. Due to political manipulation, this scheme can also be used in the case of economic, social or even terrorist manipulation. We do not have access to data about such schemes, but they certainly exist. These areas are not dispersed, but there is an interconnection and influence between each. Social manipulations are reflected in the economy, the economics of society, the reactions of society and implicitly, the safety of citizens, as terrorist manipulation manipulates the trust of the population and strongly influences the economic and political area: certain unsustainable social needs to potentiate the importance of terrorist attacks to the extent of society's dissatisfaction. These can have a great impact, with local, national or global influences: for example, a terrorist action dressing the globe's environmental action can become an extremely easy and profitable source of finance.

Figure 6. Manipulation forms, shift and interferences
(Source: Authors conception)

This case highlights a very real and very worrisome issue: the reaction to this scheme was felt only at the level of the authorities, and Facebook users did not have a prompt reaction to amend these practices. Understanding the power of such manipulation, the mechanisms and the possible consequences, but also the connection between some simple data and the power given by these databases and their use for unfair purposes or the link between the simple postings of a user and very important elements of economic, social, political or safety evolution from the individual to the interstate level cannot be perceived.

Each of us, as Internet users, can help create a safer virtual space by implementing additional measures against cyber-attacks. Max Goodberg believes it is an urgent "*technical literacy of the general public*" by running programs to promote full encryption of internet traffic and to educate society on the safe use of the Internet, but they would not be possible without unified legislation regarding cybernetics crime. He considers that the issues that should be taken into account in the legal provisions should be protection against the sale of personal information on the Internet and the publication of the vulnerabilities of a system.

An expanded ability to respond to computer aggressions and implicitly, to secure virtual environments should take into account a constant education of all users. They should be aware of the dangers they are personally exposed to or the way they are vulnerable to a community, even a state, through cyber-security actions or inactions is at risk. Together with users, developers of software and technological equipment should find the way to have early security alerts, to develop permanently and in a sustained manner the tools to fight against computer aggression attempts in collaboration and cooperation with state institutions and with respect for citizens' rights and freedoms in the virtual and real world environment. We believe it is necessary to create a warning function implemented by online application developers and create a warning registry where users can individually report possible fraud attempts, cyber security incidents, or even non-compliant practices. The law will need to be amended to ensure that there is a global level of non-conforming concepts of how to report these incidents, but also the authorities' response to collaborators with the developers of the risk-creating applications.

The main directions of action should be to modify and adapt the legislation, to the unitary control, supervision and action procedures, supported by a permanent and sustained education of all involved - users, application developer and authorities, the answer to a cyber-attack can only be effective with an active and professional collaboration of the three categories.

The analysis of this phenomenon cannot be contextual in order to be relevant and sufficient, but must have the dynamics of the technological and conceptual evolutions of the users, in a geopolitical and economic context, with a constant and sustained effort of cyber intelligence officers and analysts who have the duty to observe the "*elements of finesse*" of daily changes on the geo-economic-political scene, thus ensuring the "*anchoring to the present*" of the cyber-attack investigation.

THEORETICAL CONSIDERATIONS REGARDING THE USE OF „MACHINE LEARNING”. CONCEPTS AND PARADIGMS FOR ADVANCED TECHNOLOGY ORGANIZATIONS

Marian Sorin IONESCU

Politehnica University of Bucharest
313 Splaiul Independenței, Bucharest, Romania
marian.ionescu@man.ase.ro

Abstract. *The highly complex phenomenology approached by modern business models makes them difficult to understand, model and solve, without interdisciplinary tools, taken from the adjacent scientific field of competence, such as „Artificial Intelligence”. The elaboration of mathematical models for the study, understanding and solving of the theoretical issues of operational-strategic applied business models is the most important paradigm of the scientific thinking that makes the transition to the economic performance generated based on the rational decisions with an optimal degree of efficiency developed by the top organizational management. Artificial Intelligence is the scientific branch that provides an infinite horizon for building algorithms, procedures and mathematical models of computing, with wide applicability in business and economic issues.*

Keywords: *Artificial Intelligence; Machine Learning; Data Mining; Support Vector Machine.*

Introduction

The choice of this study is the "Machine Learning" area applied to the operational-strategic business models, with the notions, concepts and paradigms specific to the field. This entity of Artificial Intelligence knows the greatest development in computer sciences applicable to a variety of challenges coming from the economic macroenvironment. Along with "Machine Learning", the study of economic processes specific to advanced technology organizations has seen a growing development with the help of disciplines underlying Artificial Intelligence, such as „Data Mining”. This has stimulated the development of related fields such as "Pattern Recognition" (recognition of forms, patterns) and "Mathematical Statistics", modern, flexible, easily transposable, software-deployable tools used to develop successful business models involved in the processes of generating superior organizational added value.

The fundamental „target” of DATA MINING, inductive inference, „forecasting” based on operational examples is approachable through a multitude of different paradigms and techniques. Some of these raise major operational difficulties within the implementation processes, others are systemic processes structured on the classical cybernetic "black box" concept. A punctual but generic, powerful and with a high-efficiency level case is that of the "Support Vector Machine" (S.V.M.) which has proven to be relatively simple to implement within the advanced economic technology organizations applications.

The results of the activity of the economic organizations who have chosen this approach being achievements from good to excellent, compared to other approaches of the same type. The concept is introduced by Cortes & Vapnik, 1995, Boser, Guyon and Vapnik

1992. Support Vector Machine is a well-argued mathematically and complexly classification technology, applications to advanced economic technology organizations are favored by numerical data to be processed, interpreted and analyzed from the organizational economic performance perspective.

The technique underlying this type of approach is to identify a separating line, called the "maximum margin hyperplane", this leads to a process of separation between current data. The process does not always have a high degree of relevance, the fundamental use in artificial intelligence processes subsequently translated for economics models, actively and directly participate in the transformation of data into a different space where the dividing line is rigorously defined.

Designed for operationality in classification issues that occur in high technology process management, characterized by a high degree of complexity, subsequently paradigms of approach are extrapolated to regression tasks, the classification process is based on identifying the location to the division line where the new data is recorded.

Support Vector Machines are, for example, usable in data with a high degree of complexity, recognition of internal economic organization documents, facial recognition for the Human Resources Department, image classification. Precision level in such applications exceeding that of classical neural networks used in processes modeled with the help of Artificial Intelligence. S.V.M. presents economically measurable technological performances at the level of complexity of choosing features, algorithms for the extraction of specific features are identified in their system structure, a technology for identifying the proportion of white pixels in each internal document of an advanced economic technology organization is developed.

Among the advantages of the operational applications of S.V.M. within the used business models, it is necessary to specify the higher speed of classification of the new data, therefore the approach is operational with performant results even for a mix of data categories, the size of S.V.M. is from robust to very high. Comparing Support Vector Machines with Bayesian classifiers and decision trees, S.V.M. raises the issue of implementation complexity. It is possible that the classification process conducted with a S.V.M to contain a relevant degree of performance, but simultaneously it has a transparent degree of data for the low human decident factor. The amount of information provided to the economic organization in these cases is large enough in order for the approach to be operational-functional. Other types of approaches used in the specialized scientific literature are graphs and decision trees, competitors of the Support Vector Machines that provide much more efficient results in operational cases with low data volume.

Another vulnerability identified in the present study to address the issue of advanced technology organizations with S.V.M. is the lack of on-line access, the update process is re-initialized each time new training data appears. However, addressing processes specific to business models requires a high degree of understanding of algorithms and mathematical methods from top management decision makers. By identifying the business processes specific to the technological economic organizations as having the availability implementation and transposition into operation of some learning predictors in large spaces generated by the economic macroenvironment. We consider that it is necessary the position within the support vector machine paradigm (S.V.M.)

(see several studies such as Shalev-Shwartz, 2007; Shalev-Shwartz, Shamir & Sridharan, 2010; Shalev-Shwartz & Ben-David, 2017).

In the "Machine Learning" approach to business models, support vector machines, S.V.M., are supervised learning models with associated learning algorithms, thus analyzing the data used in the analysis and classification processes of the involved economic entities. An S.V.M. trainer algorithm type is built based on a model that assigns new operational case studies to a particular type of technology economic organization, transforming it into a non-probabilistic linear classifier. S.V.M. model types are a formalism as marks (points) in space (the external business environment), the examples of the categories are separated through as large as mathematically possible spread.

Image, Identification	THE EFFECTIVENESS OF APPLYING THE SUPPORT VECTOR MACHINE	Analyzing Economic Processes Making Them More Efficient
Classic Text Hyper Text Categorization		Digital Signature Recognition
Image Hierarchy		Systemic Generalized System Prognosis
Computerized Operational Processes		Macro Business Environment

Extrapolating the linear classification phenomenon, S.V.M., is the non-linear classifier of phenomenology of business processes specific to the technological economic organizations, the use of algorithms and kernel procedures mapping the inputs into large, possibly infinite spaces.

In the operational practice of the technological economic organizations there is the possibility that the data is not labeled, the supervised learning process becomes very difficult to implement, the correct approach for these cases is unsupervised learning, the used cognitive technology searches for the natural grouping of the data to the groups, the new economic data used are grouped into the already formed entities.

For this type of algorithm, we have to mention the Siegelmann and Vapnik support vector grouping algorithm, it applies the support vector statistics in the support vector machine algorithm for the classification of the non-labelable data used by the technological economic organization, the algorithm is one of grouping with the widest spread within the organizations economic actors in the IT environment and the modern industrial one.

The dimensionality of the characteristic (proper) business processes space is determined both by the complexity of the economic entities used (data, samples), but also by the complexity challenges of specific computational processes, specific to the S.V.M. algorithm. is to address the complexity of economic evidence by identifying as large as possible margin separators.

The macroeconomic space in which the technological business phenomenon is operational is identifiable by about half of the surface as a possible set of training.

Learning and testing with a larger dimensional margin, the concrete cases of used technological business models being positioned not only on the right side of the hyperplane, but on the other one too, we observe that in a marginalization process, limiting the algorithm generating a large margin separator.

It is possible to develop a representative sample of relatively small complexity, spatial characteristic being large, with the possibility of development to infinity. In the operational applications of business models used by technology economic organizations, even in the case of function space with increased dimensionality. The complexity is diminishable by limiting, restricting the outputs generating algorithm for larger margin dividers. Thus, we introduce the concept of margin, which it is reported to the regularized paradigm that aims to minimize the losses, but also to the convergence rate of the Perceptron algorithm for such economic processes. Challenges coming from specialized markets, components of a macroeconomic structure that is undergoing globalization and a growing dynamic development, demand a computing power and data storage within the economic business technology organizations.

The fundamental idea pursued by top decision makers in close collaboration with the managers of research development departments, is that of transforming algorithms and data use technologies into a direct economic advantage, quantified in higher rates of earned profits.

Figure 1. Transforming algorithms, use technologies into economic advantage

The formally chosen operational developed model has the following structure:

Domain Multitude: Let an arbitrary set, X , this is a collection of objects that are desired for a labeling process, the range of points is represented by an image vector, otherwise it is represented by value points, and X is a space of these values.

Label set: Labels set is restricted to two numeric values, $\{\pm 1\}$, and Y is the set of possible labels.

The learning data: $S = ((x_1, y_1), \dots, (x_m, y_m))$ is a finite sequence of pairs of $X \times Y$, a sequence of the labeled point range, is the input level at which the person that learns, inures, has access.

Learning outcomes: In the end of the learning process, a "predictive rule" must be issued, $h: X \rightarrow Y$, also known as a "predictor" or "hypothesis," this is used for predicting point labels in the new defined domain.

Simplified Data Generation Model: The values generated with a certain distribution probability are acquired (assumed), representing the business macroenvironment. We introduce the probability distribution on the X set of D , within the learning process everything is known about the distribution, we consider that there is a correct labeling function $f: X \rightarrow Y$, with the property $y_i = f(x_i), \forall i$, each pair used in the learning process from the data set S is generated through a sampling process started in x_i in accordance with D labeled with the help of f .

Quantification of success: We introduce the notion of "classification error" as the probability of not correctly predicting the label for points representing random data generated by the aforementioned underlying distribution.

Having a subset of domain, A included in X , the condition is that A belongs to a σ -subalgebra of X on the D -domain of definition, with the probability of distribution, assigning a numerical value $D(A)$, representing the probability of observing a point $x \in A$. A is perceived as an event and expressed using a function $\pi: X \rightarrow \{0, 1\}$, with $A = \{x \in X: \pi(x) = 1\}$, using the notation $P_{X \sim D}[\pi(x)]$ to express $D(A)$.

The predictive rule of error, $h: X \rightarrow Y$, is thus defined by the formalism

$$L_{D,f}(h) = P_{x \sim D}[h(x) \neq f(x)] = D(\{x: h(x) \neq f(x)\}).$$

This type of formalism is also identifiable with the notion of "generalized error", the risk or "true error of h ".

Information valid for the learning process: Within the learning process, there is a null perceptive about the distribution of D throughout its entire course and with the labeling function f . We identify the only way through which the "learner" can interact with the environment is to observe the multitude of forming, learning, training.

The Hard - S.V.M. concept, its application in business models

We consider that at the level of the operational activity of the technological economic organization, $S = (x_1, y_1), \dots, (x_m, y_m)$ is a set of concrete cases in the business environment, for each $x_i \in R^d$ and $y_i \in \{\pm 1\}$.

We note that this multitude of concrete cases of training, learning are linearly separable under the condition that there is half the space, (w, b) such that $y_i = \text{sign}((w, x_i) + b)$, for any i the condition can be presented otherwise $\forall i \in [m], y_i((w, x_i) + b) > 0$.

The totality of the space halves (w, b) satisfying these conditions are submissive to E.R.M. hypotheses, if "0 - 1", the error is zero, this represents the minimum possible error. The concept of „Hard - S.V.M.“ is the learning rule in which a hyperplan of E.R.M. which separates the learning set of the operationalized business process with the greatest possible margin, for a structuring and defining process it is necessary to express

the distance between an arbitrary x point of the hyperplan using the semispace definition parameters.

Thus, a distance between a point x and the hyperplane defined by (w, b) where $\|w\|$ is $|(w, x) + b|$.

HARD - S.V.M. Rule is formulated as a square optimization problem. We identify the objective as the elaboration of an optimization process, the objective is a square convex function subject to constraints in the form of linear inequalities. We propose below an operational software structure for the conceptual HARD - S.V.M., previously presented.

$$\begin{aligned}
 & \text{HARD - SVM} \\
 & \text{input: } (x_1, y_1), \dots, (x_m, y_m) \\
 & \text{calculated: } (w_0, b_0) = \underset{(w, b)}{\operatorname{argmin}} \|w\|^2, \text{ s. t. } \forall i, y_i((w, x_i) + b) \geq 1 \\
 & (1) \\
 & \text{output: } w^\wedge = \frac{w_0}{\|w_0\|}, b^\wedge = \frac{b_0}{\|w_0\|}
 \end{aligned}$$

(Shai Shalev-Shwartz and Shai Ben-David, Understanding MACHINE LERARNING)

It is shown that the output of HARD - S.V.M. is the separated hyperplan with the largest margin, we notice that the outputs of HARD - S.V.M. are solutions of the equation: $\underset{(w, b): \|w\|=1}{\operatorname{argmax}} \min_{i \in [m]} y_i((w, x_i) + b)$, which under the constraints $\forall i, y_i((w, x_i) + b) > 0$, represents the HARD - SVM Rule.

It should be remembered for the accuracy of the discussion the homogeneous case and the complexity of the pattern, sample, HARD - S.V.M.

In the case of homogeneity, the choice made reflects more flexibility in the case of homogeneous halves, the spatial halves that contain the origin, by definition the term with $\operatorname{sign}((w, x))$, the term "bias" b is set to (chosen) with a "0" value, and the HARD - S.V.M. structure for half of homogeneous spaces satisfies the relationship:

$$\min_w \|w\|^2, \text{ s. c. } y_i(w, x_i) \geq 1 \quad (2)$$

In the case of regularizing the bias term, the resulting equation is a possible optimization of the economic processes specific to the studied advanced technology organization. If the bias term is not regularized, the optimization problem, (1) is not solved even if half of homogeneous learning space, R^{d+1} , is used, in the case of the complexity of the sample HARD - S.V.M., it should be recalled that the V.C. - dimensionality within the space half belonging to R^d is $(d + 1)$.

We observe that the fundamental learning theorem specifies if there is a significant number of examples smaller than $\frac{d}{\epsilon}$, in this case there is no ϵ accuracy learning algorithm in the half of the allocated space, we introduce the following definition:

Let D be a distribution process placed on $R^d \times \{\pm 1\}$, we assert that D admits a margin separation process (γ, ρ) if there exists (w^*, b^*) , astfel incat $\|w^*\| = 1$, such that with probability 1, along the choice $(x, y) \sim D$, there is the relationship:
 $y((w^*, x) + b^*) \geq \gamma$ si $\|x\| \leq \rho$.

Analogously, we assert that D is separable by the margin (γ, ρ) using half the homogeneous space having the form $(w^*, 0)$.

Observation: Considering D the distribution for $R^d \times \{\pm 1\}$ which is satisfying the separability condition (γ, ρ) with the marginal hypothesis using half of the homogeneous space. With a lower probability of $(1 - \delta)$ for choosing the learning set, training, with size m , the output quantifiable error for HARD - S.V.M. is at most,

$$\sqrt{\frac{4(\rho/\gamma)^2}{m}} + \sqrt{\frac{2 \log(\frac{2}{\delta})}{m}}.$$

We observe that for HARD - S.V.M. expression we assume that the set of learning-training is linearly separable. We present below a simplification of the HARD - S.V.M. exigencies that are applicable also in cases where the learning-training set is not linearly separable, thus, it is possible an exhaustive coverage of the totality of cases. Both cases, linearly separable or non-linearly separable, are identifiable within the operationalities and strategic developments specific to advanced economic technology organizations.

$$\begin{aligned} & \text{SOFT - SVM} \\ & \text{input } (x_1, y_1), \dots, (x_m, y_m) \\ & \text{parameter } \lambda > 0 \\ & \text{solution: } \min_{w, b, \xi} \lambda \|w\|^2 + \frac{1}{m} \sum_{i=1}^m \xi_i \\ & \text{s. c. } \forall i, y_i((w, x_i) + b \geq 1 - \xi_i, \xi_i \geq 0 \\ & \text{output: } w, b \end{aligned} \quad (3)$$

(Shalev-Shwartz & Ben-David, 2011, p.171)

Taking into account the regularized problem of minimizing losses, we assert that (3) is equivalent to the mathematical formalism:

$$\min_{w, b} (\lambda \|w\|^2 + L_s^{\text{hinge (pivoting)}}(w, b)) \quad (4)$$

Where $L_s^{\text{hinge (pivotant)}}((w, b), (x, y)) = \max\{0, 1 - y((w, x) + b)\}$, represents by definition the losses generated by "hinge (pivoting)".

It is more convenient to consider SOFT - S.V.M. specific to the learning processes for half space, where the bias term b is set to zero, the optimization problem is formulated as follows:

$$\min_w (\lambda \|w\|^2 + L_s^{\text{hinge (pivot)}}(w)) \quad (5)$$

where:

$$L_s^{\text{hinge (pivot)}}(w) = \frac{1}{m} \sum_{i=1}^m \max\{0, 1 - y(w, x_i)\}$$

Support vectors, obtaining conditions of optimality

The name of S.V.M., "Support Vector Machine", is induced by the HARD - S.V.M. solution, w_0 has sustainability generated by operational cases located at a distance of $\frac{1}{\|w_0\|}$ from the separation hyperplan, the vectors generated are referred to as "Support Vectors". Economic applications specific to advanced technology economic organizations are structured on Fritz John's optimality conditions. The conditions are presented below.

Sentence: We consider w_0 defined as in relation (2), let $I = \{i: |w_0, x_i| = 1\}$, there are coefficients $\alpha_1, \dots, \alpha_m$, such that that $w_0 = \sum_{i \in I} \alpha_i x_i$, Support vectors are identifiable in structures $\{x_i: i \in I\}$.

Fritz John's Observation: Suppose $w^* \in \operatorname{argmin}_w f(w)$, s. c. $\forall i \in [m], g_i(w) \leq 0$, where $f, g_1, \dots, g_m$ are differentiable, then there exists $\alpha \in R^m$, such that $\nabla f(w^*) + \sum_{i \in I} \alpha_i \nabla g_i(w^*) = 0$, where $I = \{i: g_i(w^*) = 0\}$.

The Stochastic Gradient Descendent (S.G.D.) for minimizing the risk function

We define the operational-functional risk function that occurs during learning processes specific to economic processes, as being expressed by mathematical formalism:

$$L_D(w) = E_{z \sim D}[l(w, z)],$$

We observe that the empirical risk minimization method, $L_s(w)$ as an estimate of the minimization $L_D(w)$. We propose the following operational software structure:

The Stochastic Gradient Descendent, S.G.D., for minimizing $L_D(w)$

parameters: scalar $\eta > 0$, integ $T > 0$

initialization: $w^{(1)} = 0$

for $t = 1, 2, \dots, T$

(sample) $z \sim D$

(pick) $v_t \in \delta l(w^t, z)$

(update) $w^{(t+1)} = w^t - \eta v_t$

output $w^- = \frac{1}{T} \sum_{t=1}^T w^t$

(Shalev-Shwartz & Ben-David, 2011, p.177)

Implementation of SOFT - S.V.M. using the S.G.D.

In the operational practice of the technological economic organizations solving the optimization problem for SOFT-S.V.M becomes a central problem., this admits a representation in the form of the mathematical expression:

$$\min_w \left(\frac{\lambda}{2} \|w\|^2 + \frac{1}{m} \sum_{i=1}^m \max\{0, 1 - y(w, x_i)\} \right) \quad (6)$$

We propose for the regularized problems of minimizing losses a S.G.D. frame implemented software as below.

For loss of "hinge" applications we choose v_j as being 0 if $y(w^{(j)}, x) \geq 1$ and $v_j = -y x$ otherwise, noting $\theta^{(t)} = \sum_{j < t} v_j$.

S.G.D. for solving SOFT - SVM

goal: resolving the optimization equation SOFT - SVM

parameter: T

initialize: $\theta^{(1)} = 0$

for $t = 1, \dots, T$

let $w^t = \frac{1}{\lambda t} \theta^{(t)}$

we choose i randomly uniformly from $[m]$

if $(y_i(w^{(t)}, x_i) < 1$

set $\theta^{(t+1)} = \theta^{(t)} + y_i x_i$

else

set $\theta^{(t+1)} = \theta^{(t)}$

$$\text{output: } w^- = \frac{1}{T} \sum_{t=1}^T w^{(t)}$$

Approach with "Kernel Methods (cores)"

In computer-specific learning processes, "Kernel methods" are a set of algorithms for model analysis, we identify the S.V.M support vector machine. The model has the fundamental objective to identify and analyze the general typology of relationships, clusters, hierarchies, correlations, transformation into series of data. The algorithms of this type are explicitly transformed into vector representations that provide a presentation of the user-specific features. In the case of Kernel's Methods, it is required only one user-specified kernel, a similarity function on pairs of rough representation points. Under Kernel Methods, operation is allowed in a characteristic dimensional implied space, without developing a process of calculating data coordinates in that space. The operation is thus in terms of financially acceptable allocation, costs are greatly reduced, in scientific literature this approach is called the "kernel trick", kernel functions are introduced for sequential data, graphics, text, images, vectors.

Among the algorithms used in analyzing and solving business issues specific to advanced technology economic organizations, we recall S.V.M., GAUSS processes, the processes of the Principal Component Analysis (P.C.A.), the canonical correlation analysis, ridge regression, spectral grouping, linear adaptive filters. The totality of linear patterns is transformable into nonlinear models by applying the concepts and paradigms specific to the "kernel trick", replacing its features, predictors, with the kernel function.

We observe that the totality of kernel algorithms is based on convex optimization, statically well argued, their static properties are studied through static learning theory, a way of approach is the RADEMACHER complexity. The fundamentals of this type of approach are structured on the idea of incorporating data into a high dimensional characteristic space. A core („kernel") is a measuring type of the similarity between sequences, they are perceived as HILBERT's inner space products, the instant space is virtually incorporated.

We consider the field of data used by the advanced technology economic organization as being the real number axis, limited to a certain set of numeric values, $\{-10, \dots, 0, \dots, 10\}$, the labels for the total $|x| > 2$ are +1 and -1 otherwise. A learning process for half space, in its initial representation, is replaceable by using a function $\psi: R \rightarrow R^2$, having the formalism, $\psi(x) = (x, x^2)$.

We call the characteristic space of the function set ψ , half of the space is characterized by the relationality, $h(x) = \text{sign}((w, \psi(x)) - b)$, where the corresponding numerical values are $w = (0, 1), b = 5$.

The approach model used, so the thinking paradigm within the "Kernel Methods" is developed on the following hubs:

- considering a lot of X domains, a learning task (objective), choosing mapping, $\psi: X \rightarrow F$, for a characteristic space F , operational from R^n , for certain n values.
- we consider a lot of labels, $S = (x_1, y_1), \dots, (x_m, y_m)$, the images sequence is generated, $S^\wedge = (\psi(x_1), y_1), \dots, (\psi(x_m), y_m)$
- is prepared, trained a linear type predictor, h during $S^\wedge$.
- the label of a test point, x , is predicted to be expressed by $h(\psi(x))$.

Several studies address these aspects (Shalev-Shwartz, Shamir & Sridharan, 2010; Japkowicz & Shah, 2011).

The Kernel innovative approach

Specifically, to the economic activities, incorporating entry space into a large size space, make the learning process in half the space more efficient. The complexity of computational processes, a feature of advanced technology organizations, for learning activities represents a linearly efficient computerized data separator, usable for large volumes of information-data to process, induced processes requiring significant financial allocations.

The concept of „kernels” („cores”) is used for a proper description of the interior products in the characteristic space, having a functional relationship ψ and an area of space X positioned in a HILBERT space is defined as the „kernel” („core”) in the form of the relationality $K(x, x') = (\psi(x), \psi(x'))$, we observe K an argument expressing the similarity between sequences and the incorporation mode ψ as a mapping of the set domain X , positioned in a space where the two similarities are inner products (Shalev-Shwartz, Shamir & Sridharan, 2010). Many algorithms specific to learning half-space processes are made based on the value of the kernel-expressing function, the structuring is done on pairs of points in the field, we identify a main advantage of this type of algorithmic approach, the implementation of linear separators in large dimensionalities spaces, without specifying the points located in that space or the expression ψ incorporated into that space.

We note that the totality versions of the S.V.M. are specific situations of the general form:

$$\min_w \left(f((w, \psi(x_1)), \dots, (w, \psi(x_m))) + R(|w|) \right) \quad (7)$$

in which $f: R^n \rightarrow R$ is an arbitrary function and $R: R_+ \rightarrow R$ is a non-decreasing monotonous function.

In the operational economic applications, it is necessary to substantiate the decisions with the help of a sentences of fundamental truth, "Theorem of Representation".

The Representation Theorem: Assuming that ψ is a („mapping”) a lui X in a HILBERT space, then there exists a vector $\alpha \in R^m$, such that $w = \sum_{i=1}^m \alpha_i \psi(x_i)$, which represents an optimal solution for the equation (7).

Specifying the previous presentation of SOFT - S.V.M., as in equation (5), the problem is reformulated as:

$$\min_{\alpha \in R^m} (\lambda \alpha^T G \alpha + \frac{1}{m} \sum_{i=1}^m \max\{0, 1 - y_i(G\alpha)_i\}) \quad (8)$$

where $(G\alpha)_i$ is the i^{st} element of the vector obtained by multiplying the GRAM matrix, G with the α vector, we notice that equation (8) is in the form of a square program, so an efficient solution exists.

The coefficients α are calculated for forecast, prognose for a new sequence, as follows:

$$(w, \psi(x)) = \sum_{j=1}^m \alpha_j (\psi(x_j), \psi(x)) = \sum_{j=1}^m \alpha_j K(x_j, x)$$

In the case of the concrete operational situations of the advanced technology organizations, addressing the problems arising from the business environment with the help of the "kernel method" rather than inducing a directly process of optimization w in the characteristic space is supported by the fact that in certain concrete cases, the size of the characteristic space is extremely high on the time axis, the implementation of the "kernel method" is simple and extremely flexible.

The kernel perception as a way of expressing previous knowledge

A mapping of the ψ characteristics is perceived as an extrapolation of the linear class to a larger one, corresponding to the linear classifiers out of the characteristic spaces. We observe that the adequacy of any set of assumptions, hypotheses about the task of learning objectively depends entirely on the nature of this type of task. We develop a paradigm of thinking in which the incorporation of ψ is perceived as a way of expressing and using the knowledge available to the top organizational decision-maker regarding the challenge to be solved. There is a possibility that the learning task can be used to identify a sequence of characters, „signature“, in a data file that made available to the top organizational decision maker, indicating a virus that alters the quality of the information or not.

Formally, we consider X a set of strings finite on a set of alphabet Σ , and let X_i the set of all strings with a maximum length d , the set of assumptions, working hypotheses wanted to be learned is $H = \{h_v: v \in X_d\}$, where for a string $x \in X$, $h_v(x)$ is 1 if v is a substring of x si $h_v(x) = -1$, otherwise. We consider a mapping function ψ on the space R^s , where $s = |X_d|$, the coordinates of $\psi(x)$ on the space R^s , where $s = |X_d|$, the coordinates of $\psi(x)$ correspond to a few strings v , they indicate if v is a substring of x , this means for any $x \in X$, $\psi(x)$ is vector in $\{0, 1\}^{|X_d|}$.

Each member of the set H is achievable by composing some classifiers on $\psi(x)$, more than one half of the space, with the norm 1 and reaching the margin of 1.

For each $x \in X$, $\|\psi(x)\| = O(\sqrt{d})$, the learning process is developed using S.V.M., a pattern sample of complexity showing that it is polynomial in d .

At the level of the applications specific to the advanced technology economic organizations, we find that the dimension of the characteristic space is exponential for d , the implementation by S.V.M. becoming a difficult process. We observe, however, that there is a computing feature of the inner product within the characteristic space, the kernel function, without an explicit cartographic presentation of the characteristic spatial sequences. We observe $K(x, x')$ as the number under the strings of x and x' easy to calculate for a corresponding time allocation for the polynomial d . It is thus demonstrated the mapping mode of the features, thus allowing spaces allocated for non-vectorial domains.

Kernel functions characteristics

The kernel matrix is a way of expressing the previously acquired knowledge. We consider a similar function given by the form $K: X \times X \rightarrow R$, the problem that arises is the possibility of representing an inner product between $\psi(x)$ si $\psi(x')$.

Observation: A symmetric function $K: X \times X \rightarrow R$ implements an inner product in certain HILBERT spaces if and only if it is positive semi-definite, called for the totality $x_1, \dots, x_m$, GRAM matrix, $G_{i,j} = K(x_i, x_j)$ is a positive semi-definite matrix.

Discussion: It is obvious that if at K level an inner product is implemented in a HILBERT space, it results that the GRAM matrix is positively semi-defined.

Extrapolating the discussion for the totality of possible operational situations, defining spatial functions over X as $R^X = \{f: X \rightarrow R\}$, for each $x \in X$, let $\psi(x)$ is the function $x \rightarrow K(\cdot, x)$.

We define a vector space taking the totality of linear combinations of $K(\cdot, x)$ elements, an inner product of this vector space admits a representation of the form;

$$\left(\sum_i \alpha_i K(\cdot, x_i), \sum_j \beta_j K(\cdot, x'_j) \right) = \sum_{i,j} \alpha_i \beta_j K(x_i, x'_j)$$

We affirm that this is a valid inner product as long as it is symmetric, property correlated with the symmetry of K , the product presented is linear and positively defined.

Result:

$$(\psi(x), \psi(x')) = (K(\cdot, x), K(\cdot, x')) = K(x, x')$$

Implementation of SOFT – S.V.M. with kernel, proposed model

Previously presented was the challenge of SOFT - S.V.M., the approach with the help of the "Kernel Method" is the subject of the scientific analysis developed further.

Equation (8) admits an algorithmic solution, but a simpler way to solve it is to address the problem of SOFT – S.V.M. optimization in spatial or characteristic,

$$\min_w \left(\frac{\lambda}{2} \|w\|^2 + \frac{1}{m} \sum_{i=1}^m \max\{0, 1 - y(w, \psi(x_i))\} \right),$$

(9)

using kernel ratings.

We note that vector $w^{(t)}$ introduced by S.G.D. procedure (Stochastic Gradients Descent) previously introduced is always in the linear span of $\{\psi(x_1), \dots, \psi(x_m)\}$, maintaining of $w^{(t)}$ is equivalent to maintaining the correspondence of coefficients α .

We define $K(x, x') = (\psi(x), \psi(x'))$, $\forall x, x'$, maintaining two vectors of R^m , corresponding to two vectors, $\theta^{(t)}$ and $w^{(t)}$ defined in the S.G.D. procedure $\beta^{(t)}$ is a vector such that

$$\theta^{(t)} = \sum_{j=1}^m \beta_j^{(t)} \psi(x_j) \quad (10)$$

si $\alpha^{(t)}$ is such that

$$w^{(t)} = \sum_{j=1}^m \alpha_j^{(t)} \psi(x_j) \quad (11)$$

The two vectors α, β are subject to an update process according to the proposed later procedure.

S. G. D. used to solve SOFT – S. V. M. with Kernel

$$\text{Purpose: solution } \min_w \left(\frac{\lambda}{2} \|w\|^2 + \frac{1}{m} \sum_{i=1}^m \max\{0, 1 - y(w, \psi(x_i))\} \right)$$

parameter : T

initilialization: $\beta^{(1)} = 0$

for $t = 1, \dots, T$

let $\alpha^{(t)} = \frac{1}{\lambda t} \beta^{(t)}$

let i uniformly randomly from $[m]$
 for all $j \neq i$, we choose $\beta_j^{(t+1)} = \beta_j^{(t)}$
 if $(y_i \sum_{j=1}^m \alpha_j^{(t)} K(x_j, x_i) < 1)$
 we choose $\beta_i^{(t+1)} = \beta_i^{(t)} + y_i$
 otherwise
 we choose $\beta_i^{(t+1)} = \beta_i^{(t)}$
 (Output): $w^- = \sum_{j=1}^m \alpha_j^- \psi(x_j)$, $\alpha^- = \frac{1}{T} \sum_{t=1}^T \alpha^{(t)}$

See several studies (Shalev-Shwartz, Shamir & Sridharan, 2010; Shalev-Shwartz & Ben-David, 2017).

It is demonstrable that the previous implementation is equivalent to the launching in execution of the S.G.D. for the characteristic space.

Considering w^- - the outputs of the S.G.D. described above, when applied on a spatial characteristic, let $w^- = \sum_{j=1}^m \alpha_j^- \psi(x_j)$ outputs after applying S.G.D. with kernels, then $w^- = w^\wedge$.

It is obvious that for $\forall t$, the result of running S.G.D. program, $\theta^{(t)}$ is held by equation (10) within the characteristic space.

By definition $\alpha^{(t)} = \frac{1}{\lambda t} \beta^{(t)}$, $w^{(t)} = \frac{1}{\lambda t} \theta^{(t)}$, the statement shows that $w^{(t)}$ is held by equation (11).

For $t = 1$ the statement is obvious, if $i \geq 1$, then:

$$y_i (w^{(t)}, \psi(x_i)) = y_i (\sum_j \alpha_j^{(t)} \psi(x_j), \psi(x_i)) = y_i (\sum_j \alpha_j^{(t)} K(x_j, x_i).$$

The condition of the two algorithms is equivalent to the updating of θ , it follows:

$$\theta^{(t+1)} = \theta^{(t)} + y_i \psi(x_i) = \sum_{j=1}^m \beta_j^{(t)} \psi(x_j) + y_i \psi(x_i) = \sum_{j=1}^m \beta_j^{(t+1)} \psi(x_j),$$

Which leads to the asserted conclusions.

Conclusions

The modern business environment contains economic organizations that operationalize and develop top technologies and even frontiers, the totality of which are faced with a strong need to increase computing power and storing used business data. From the perspective of the business models developed and implemented, it means that the vast majority of the economic organizations currently have very large size archives of data and information products, the human decident is most often overwhelmed by them. The challenge addressed to the top organizational decision-maker is to transform the huge volume of corporate data into an economically competitive advantage.

By translating the solving of some of the problems from the engineering sciences in the economic field, common applications are developed, from the anticipation of the products with a high degree of purchasing possibility by a client, the answers elaborated on the basis of questionnaires. Operational, engineering and economic reality imposed „Data Mining“, a component of Artificial Intelligence, related field to „Machine Learning“, Model Recognition, Mathematical Statistics, „Data Mining“ performs a part of the suboptimal and random analyzes needed to develop the decision making process,

regardless of its positioning within the structure of the studied advanced technology economic organization.

It is a unique possibility of strategic development of the new field, the arguments that offer this opportunity are the very large numbers of algorithmic approaches and algorithmic paradigms available. The fundamental task of „Data Mining” is that of inductive inference, prediction based on operational realities, approachable through a variety of different techniques. The degree of complexity of these paradigms requires human resourcing departments, involves high-skill entities, and their simplification often leads to "black box" approaches.

Vector Machine Support – S.V.M. is a method with a high degree of generality, efficiency, and powerful mathematics, generating results which at the outputs of the „output data” processes are evaluated from good to superlative, even optimal, compared to addressing issues through other methods. Understanding and transposing in operability of the concepts and paradigms of S.V.M., requires that there is a high standard of mathematical education at the level of top organizational management. The present study identifies and presents the relationship between S.V.M. and the scientific methods of analysis of the approached business issues, for the economic organizations using top I.T. and virtual technologies. Also described are the ways and algorithms needed to transpose in operability the S.V.M., the set of guidelines and the fundamental rules for the application of the S.V.M. concept, in all complexity and with all the advantages that result from it are specified. The theoretical and applicative considerations of the present scientific investigation, without claiming to be exhaustive, introduce the ideas, the methodology, as well as a succinct presentation of the specific software structures of S.V.M., intended for the applications. The general problem is that of induction, an important one that generates significant added value for organizational databases. The analysis and understanding of the existing correlations within these databases is a fundamental one with a high degree of complexity, flexible and relatively easy to implement operationally, the case of S.V.M. study. The S.V.M. approach is based and further developed on a simple and intuitive concept involving the separation of the two data classes in the first part using a linear function that shows the maximum distance of the used data.

The idea then becomes a powerful and efficient learning algorithm, when the problem of separability (marginal errors) and the implicit mapping of characteristic, more descriptive spaces by operationalization of the kernel functions are overcome. At the operational-strategic level, software packages are developed which allow for their implementation and launch in operational life, obtaining very good results with human effort and minimal organizational allocations. Taking into account the accelerated scientific progress, the complexity of the problems and challenges coming from the economic environment, as well as the competition of the economic organizations and the development of business models, well founded theoretically, we consider the field to be just in the beginning, major future developments becoming inevitable.

Abstract. *The course of the relationship building process that may turn out to be the key element depends on several factors, for example the behavior and style of human being, both the customer and the salesperson, the form of sales, networking of business and marketing processes, building trust between the parties, as well using the latest IT solutions in the sales process. In the contemporary world of business, where the Internet is a very important medium for the promotion of an enterprise, brand or product, various IT systems help in managing the customer information or adapting the offer for him/her. In the article the authors will try to present the following elements in the area of creating customer relations: basic assumptions of the concept: client-relationship-IT environment, identification of dominant attributes of the IT environment in the context of e-business, networking of business and marketing processes, virtualization of processes that enhance the value of the product in contemporary organization or enriching information resources about the product. This is a theoretical and empirical article (based on the case study of Apple company) and its objective is to show the process of building the relationship with customers in the contemporary enterprise, mainly concentrating the issue on the IT environment. The article tries to answer to, among many others, the following questions:*

- 1. What are relations with clients and types of the building relationships with customers?*
- 2. What are the basic concepts of creating the relationship between the customer and the firm in the IT environment?*
- 3. What are the determinants of good practice in the researched enterprise?*

Keywords: *relationships with clients; IT environment; e-business; IT management systems; Apple company.*

Introduction

In terms of behaviors in the "sale-purchase" process, one can find relations between the company and the customer, which are based on a variety of strategies and activities of both sides. This area is one of the most important elements of the functioning of companies because without the recipient there is no entity on the market (Ogilvy, 1983, pp.22-23). This correlation causes each party to perform its functions in the sales process, which leads to maintaining parity in the context of the strategic importance of both parties. In order to determine the current position of the client in the company's strategies, it is necessary to pay attention to the very evolution of consumer-market

contacts (Doligalski, 2013, pp.9-10). Analyzing communication between clients and enterprises, two trends can be observed in the 20th and 21st centuries. The first one depicts one-sided contact, where the company appointed a close group of clients, to which it directed its offer without conducting an open dialogue with other consumers. Since the late 1980s, the communication between the pillars described has been observable until now. Communication has become a two-way name, on the basis of which the idea of relationship marketing was created; what is more, both the customer and the company are more focused on the use of ICT technologies and systems in everyday functioning. The following figure introduces the discussed evolution of communication in building relations between the consumer and the supplier of products or services (Figure 1).

Figure 1. Communication and client-enterprise interactions over decades
(own study based on Maciejewski, 2012, pp.39-40)

Continuing the discussion on consumer relations with enterprises over the decades to come, one can distinguish another category helping to understand the evolution of the concept of "consumer, customer, buyer". The role and character of clients in the economic market can be considered, along with the perception of these groups by enterprises (Wereda, 2009, pp.50-53). This consumer viewpoint goes from mass perception to individual perception. The very role of consumer units is transformed

from passive buyers into members of the culture-forming part of enterprises who are active in cyberspace, doing most online shopping, suggesting opinions on portals, blogs or social media, and on the other hand placing their insights and seeking information in IT programs and systems. The purpose of this article is to present the process of building customer relations and improving these relationships through the IT environment, both from the theoretical side and the example of a case study.

Creating relationships with clients – theoretical overview

The basis for the customer-company relationship is a number of individual transactions between the seller and buyers, leading to an increase in the customer's sense of value. The correct cycle of relationships consists of three elements: value offer, customer satisfaction and, in effect, customer loyalty based on trust (Kotler, 2005, p.13). In connection with the above, building a customer relationship is a process that requires patience, commitment and reliability on the part of the enterprise. Building long-lasting relationships with customers is simply profitable because customers who are offended by poor service quality often do not return to the company in which they are badly served, while well-served buyers can bring new consumers to the company. According to Harker, building a solid relationship with the client consists of seven values: creation, development, maintenance, interaction, long-term, emotional content and result (Harker, 1999). What's more, a very important process in building a customer relationship is communicating with one. Many marketing authors and practitioners indicate that to be effective in communicating with the client, one should show:

- empathy;
- show proper respect to the interlocutor and take into account his/her beliefs and views;
- cordiality without intrusion;
- create bonds without elements of favor or subjectivism;
- authenticity; which means openness of behavior and freedom, sincere reactions and rejection of a defensive attitude (Burnett, 2002, p.260);
- attract attention and gain customer engagement;
- use all possible forms of mobile communication and use all the Internet functions to advocate a product and brand knowledge (Kotler et al., 2017, pp.14-15; Stawarz-Garcia, 2018, pp.10-12).

In modern relations with clients, the company must demonstrate: knowledge of the subject, conviction about the propriety, communication skills, not only in the context of vertical relations but above all in horizontal relations, that is obtaining information and knowledge from external sources, for example, consumers or market partners (prosumption). Customers should be perceived as equal to the brand of the company, i.e. as friends, and the brand should present its true character and show its value fairly, only then will both parties build credibility in a mutual relationship (Kotler et al., 2017, p.27).

An important aspect is the fact that the company can build various types of relationships with the client. Depending on the aspect of the relationship and the form of commercial transactions or behavior on the part of the company, relations can generally be divided into:

1. **Reactive relationships** consist of the fact that the company sells products to customers and encourages them to contact in case of any doubts or problems.

2. **Proactive relations** boil down to the fact that the company periodically contacts clients to inform about new products on offer or to provide suggestions for using the product. Currently, such materials are sent mainly by e-mail (e.g. in the form of newsletters or calls from the Call Centre).
3. **Responsible relationships** consist of the fact that the company contacts the customer after the purchase to check whether the product meets the expectations of the consumer. The company also tries to systematically learn about the possible improvement of the product and determine the reasons for possible dissatisfaction with the purchase. In responsible relations, communication on the company-company line takes the form of a dialogue. Such feedback allows the company to best match the offer to the customer's needs (Dejnaka, 2013, pp.396-397).
4. **Relations based on trust** consist in creating trust between the client and the company. Because this is the foundation of the mutual commitment of the parties and striving to maintain the continuity of the relationship. The occurrence of trust both within the organization and in relations with the environment is not obvious, especially in the conditions of uncertainty, crisis or the high value of the object of relational exchange (Jonczyk, 2010, p.141).
5. **Customer relations** in the network consist in conscious building positive relationships with the consumer on the Internet, from the very beginning of the company's existence on the website, also through the social media platform or creating blogs or company portals.
6. **Relations based on intercession** rely on creating in the minds of customers a sincere and honest image of a service/product provider so that in conversations about the company with other clients in the social circles, both "face to face" and online influence the purchasing behavior other people. Such social contacts have more influence on the choice of brand or loyalty to the company than false promises or advertising tricks of big marketing companies (Kotler et al., 2017, p.21).

The division of customer relations is presented below (table 1) due to different criteria and authors (Czakon, 2012, pp.49-54; Cygler, 2002, pp.163-165; Todeva, 2006, pp.160-213; Witek Hejduk et al., 2016, pp.37-41; Wereda 2009, pp.71-77).

Table 1. Classification of business relationships with clients due to selected criteria

Criterion	Type of relationship
Power on the market	relations dominated by the enterprise relations dominated by clients relations of equal partners
The degree of ordering of contacts	ordered relations (in the form of long-term commercial contracts) unstructured relations (orders are carried out continuously, but without the conclusion of commercial contracts) sporadic relationships (depending on the order) fuzzy relations (depending on market factors)
The degree of stability and mutual loyalty in relation	stable relations unstable relations relations of intercession relations of advocate loyalty
Number of contacts	frequent relations rare relationships

Criterion	Type of relationship
Geographical scope of the company's operation on the market	relationships with local clients customer relations within a regional range customer relations at the national level customer relations at an international level customer relations in a global range
Long-term relationships	ad hoc relationships created without loyalty, only for a limited time relationships created on the basis of long-term contracts
Formalization of relationships	formal relations in the form of bilateral agreements informal relations on the basis of an oral contract
The strength of the company's connections with the customer	strong relationships weak relationships
Place of transaction and relationship	off-line relations (making purchases and building relationships at stationary points) on-line relations (making purchases and building relationships only in cyberspace)
Product innovation and relationship service	quick innovation relations (focused on quick creation by companies of innovative products and offering customers before they are released on the market) slow innovation relationships (focused on creating innovative products by companies and offering customers after they are released on the market) open innovation relations (clients in the course of long-term cooperation and purchases in the enterprise become prosumers and also co-design market novelties)
Location in the value chain network	vertical relations horizontal relations mixed relations

In the contemporary business world, each enterprise must be based on a certain market orientation. Depending on what stage the company operates, the orientation indicates further activities of the organization. Currently, companies operate mainly in customer orientation, technological or business orientation. In reference to the observance of the belief that customer's needs and its satisfaction for the company is the most important, resources and processes in the organization should be subordinated to creating value for the client and building long-term relationships with one (Doligalski, 2013, p.21).

Generally, it should be noted that building customer relationships is critical to the existence of a product, brand or company on the market. It is now necessary to ask a question about what can help these relationships, so that, on the one hand, the company is sufficiently informed about the customer's needs and had customer data, and on the other hand, the buyer was able to freely obtain information about the company. All these processes can be improved by ICT. What's more, in the era of the information society, organizational models and structures are strongly determined by the tools and information technologies used, and above all communication platforms and systems that support the creation of knowledge in the company and its environment. Therefore, the relationship between the company - the customer - information resources becomes the key attribute of the operational efficiency. The information structure is an integral tool for organizing elements and logical grouping of resources (human, material, financial, information) on the basis of established and defined relations between various elements of operating systems, such as modern enterprises. In addition, the

organizational structure appears as a dynamic creation, subject to changes in accordance with the tasks and objectives and the strength of the relationship with the environment, including business partners, in particular with clients.

Basic assumptions of the concept of building and improving the customer-IT environment-enterprise relationship

The IT environment is today a real determinant of the efficiency and effectiveness of modern organizations and a prerequisite for the implementation of the concept of process organizations, based on a model of multidimensional relations, both in executive teams and relationships with clients. The communication system in the company and beyond is thus becoming the dominant component of the entire information system in the organization. Contemporary business entities often rely on working in a dispersed geographical environment and demonstrate the possibility of transferring some of the activity to the network environment with an emphasis on virtuality and multi-entity nature of process organizations. The efficiency of their functioning is often referred to as the criterion of such shaped action structures. One of the important assumptions is to expect that process structures should be favorable (Zaskorski, 2012a, pp.55-189) maximizing the synergy effect, especially in the case of multi-stakeholder organizations. The dominating attribute of modern IT tools should, therefore, be the possibility of strengthening the flexibility of operation and shortening the communication path from the manufacturer to the client and the decision processes themselves by creating conditions for the development of business entities with regard to time-cost criteria.

Contemporary information and teleinformation technologies are a potential for virtualization (Zaskorski, 2012b, pp.24-33) structures based on network and the informal combination of action entities (including clients) around shared values. An important assumption is first of all the ability to quickly adjust the company's configuration to the challenges and requirements resulting from the needs of its potential customers. Such a model should be based on a trust in the knowledge and skills of cooperating entities, which requires the introduction of standards limiting the risk of incorrect matching of tasks to the capabilities of individual co-developers of processes and, above all, customer expectations. Therefore, the activities of such an organization can be developed through the implementation of ICT technologies on the Internet platform, including the use of cloud computing services (CC/Cloud Computing).

It is worth paying attention to the important assumption about the possibility of the so-called "danetization" of all objects and processes using IoT/Internet of Things by collecting data about any object, customer or process with no time limits or geographical, but with access to the Internet (Dominique & Vlad, 2017). This means using IoT technology to monitor the so-called "smart" things that can emit information about themselves and their location. The communication platform is complemented by the so-called Big-Data systems (Zaskorski & Zaskorski, 2016), which are able to collect, store and analyze this multiform information (data, films, texts, etc.) and generate useful knowledge.

Identification of dominant attributes of the IT environment in the context of e-business

The Internet platform combined with integrated information management systems, in which CRM systems play a highly creative role - is an important challenge for modern e-business. In addition, information services can be transferred to the cloud computing (CC services) and can be scalable in relation to the needs (costs adequate to the duration of the service or the size of "consumed" information resources), which becomes an important attribute especially for smaller enterprises. The previously mentioned Internet of Things (IoT) and systems for collecting a very large number of multiform data strengthen modern management systems by providing their ability to discover knowledge (Data-Mining model) about the customer or product and market trends related to quality or even to individual phases of the cycle product life.

Figure 2. Virtualization of information services in the context of IT technology and the functionality of process-oriented organizations

Contemporary IT solutions and ICT platforms provide the opportunity for a global reorientation of information and decision processes and communication processes both within the company and its surroundings (Figure 2). Such opportunities are primarily related to access to the Internet platform and to virtual resources residing in the cloud in order to provide information business continuity (Zaskorski, 2011, pp.145-170) of a given entity. Services available on the Internet platform with access to various types of information resources and technical and technological resources in the so-called cyberspace is a great opportunity to counteract information exclusion of enterprises. Reaching for solutions related to the collection and processing of current data online (OLTP/On-Line-Transaction-Processing systems, including CRM systems) and the collection of large amounts of historical data (OLAP / On-Line-Analyzing-Processing systems) together with access to multi-aspect analyzes, it gives business entities the possibility of a flexible impact on the client-company relationship. These analyzes can be based on cluster models, behavioral similarity, time series analysis, regression analysis, etc., and give the chance to get answers to the question "we do not know what we do not know?".

For several years, access to the so-called Big-Data systems gathering large amounts of information of a global and local nature in any form with the mechanisms of their selection and knowledge discovery according to similar models, as in OLAP class

systems. These systems complement the possibility of using services and various data in the network access mode without time-space constraints. A good complement to these services may be the so-called business geoanalysis, which is related to access to geographic information systems and the use of geographical dimension for analysis, which can be dynamically redefined (region, set of countries, area within the country, a collection of selected places or cities, etc.).

As previously mentioned, the functional extension of the possibilities of obtaining and collecting data for the needs of process-oriented business organizations are IoT or more broadly IoE (Internet of Everything). These technologies belong to one of the fastest growing information technologies that can integrate various devices and objects related to the activities of specific entities in the global space. IoT/IoE are technologies that use all the advantages of the Internet and other information technologies - enabling building networks of interconnected devices (including devices connected directly with the client). Further development of this technology can become the basis for the development and effective communication process in any business space. It is worth noting here that the security of data processing and the security of the organization and its continuity are of great importance, which is conditioned by the effectiveness and credibility of information-decision processes in cyberspace. Therefore, it is necessary to take into account the resulting threats.

Implementation of process models is today a certain pattern of flattening structures in a modern enterprise. Access to common, consistent, reliable and up-to-date data becomes a prerequisite for effective operation and coordination of business operations (Timmers, 1998, pp.3-8). Network and network-centric structures (with the so-called "crawling" competence center) determine the model of communication and interaction with the client and other stakeholders of the organization. The advantages of the Internet as a universal network are well exposed, but also the limitations and weaknesses of this should be identifiable. The aforementioned possibility of cooperation of various business process executors through standardized access to a common data repository without major time and geographical constraints becomes a driving mechanism in a modern group work model and shaping a new work culture based on mutual trust in the network not only corporate but also global. This process can be enhanced by the functionality of internal and external communication systems in the company and in particular CRM class systems. A comprehensive model of this strategy is the use of resources and services located in the cloud with dedicated access for selected groups of clients, and even with the possibility of conscious (acceptable) monitoring of the behavior of a single customer or product (e.g. using Big-Data analyzes – see details on the complexity of this topic in Crişan, Zbucăa & Moraru, 2014). The systemic requirement should, however, be to protect the privacy of each client according to its indications and requirements in this respect.

Networking of business and marketing processes

Process structures and cooperation of entities as well as using the potential of other clients and stakeholders in online mode is one of the attributes of modern organizations (Fig. 2). A global network of Internet type enriched services in cloud computing today is not innovation, but still remains a phenomenon which creates opportunities for the development of information and communication services without major restrictions especially for smaller businesses. Still, technical and technological investments in the IT

area are quite expensive. Cloud computing (CC) evidently mitigates these limitations. In the era of globalization and computerization of enterprises, information and constant access to current information resources - is one of the areas of competitive struggle. This change follows the model of the communication system in companies through the wider use of network models, since in many cases, smaller companies cannot afford to buy professional equipment, and custom applications, the cost of which could be many times their financial possibilities.

Nowadays, functioning without integrated and efficient IT solutions becomes less effective regardless of the nature of the business. The network services platform (fig. 2) enriched with access to virtual, unlimited resources residing in the computing cloud (hardware, data centers, applications/software) is a technical and technological base supporting solutions to problems of both large organizations and individual entrepreneurs taking into account the current preferences of clients. The network model based on CC services (Cloud Computing) therefore fosters the informational integration of not only service and production processes, but also the improvement of more effective activities through the improvement of the communication system and contact with the client. It is nothing else than a new business model based on solutions provided in cyberspace with the possibility of creative use of the Internet phenomenon by creating a new type of process organization (Amazon Web Services, 2018). CC IT services allow to use unlimited data resources about own operations and competitors, as well as from advanced applications and the computing power available in the network without the need to incur expenditures to purchase licenses and software. These services are offered in the mode of outsourcing by external entities are an economically very profitable solution (Mateos, 2011, pp.26-27). The modern process organization based on the network model has, therefore, the possibility to market many internal relations thanks to the access to the Internet (a communication system almost without boundaries), taking into account such attributes (Mateos, 2011, pp.27-31) as:

- availability of computational resources for all registered users and the possibility of their maximum use thanks to virtualization;
- scalability of the service depending on the specific needs and adjustment of the level of costs to the resources used.

The availability of resources for registered users is adequate to the computing power used. Starting a business can be considered in principle at no cost, and then with a relatively low fee. In addition, data in the enterprise network model should be protected and secured with the appropriate level of attributes (Lidermann, 2000, p.12), data security secrecy (proper protection of information according to the level of data sensitivity), integrity (consistent, complete and reliable data) and availability (according to the accepted access rights according to the requirements of the user/customer). Depending on the nature of the business, some of the attributes may be considered as priorities (confidentiality, authenticity, and non-repudiation as necessary elements of information security).

In reference to all aspects of presenting the offer to the customer, it can be noticed that there is more and more often the product virtualization, which includes two processes: product digitization and its enrichment in information. Digitization of the product is a total or partial conversion of the product form from material to digital, exchange of atoms into bits. In each company it goes differently, e.g. airlines have only digitized part of the product, which is a ticket (replacing a traditional ticket for an electronic ticket),

however, computer equipment or the air transport service itself requires material infrastructure. Fully digitized products are characterized by zero marginal costs and are easily distributed over the Internet, which reduces the client's transaction costs (e.g. musical works that were originally inseparably connected with such carriers as a CD or cassette now appear in the form of a digitized music record between others in the form of mp3 (Doligalski, 2006). The second element of product or service virtualization is its enrichment in information, i.e. the product itself does not have to change its form, but it receives an information layer that increases its value (e.g. enrichment in information is a frequent form of innovation values on the Internet). Examples of this type of process are courier services, which are enriched with the service of identifying the current location of the shipment (Doligalski, 2013, p.81).

Apple as a leader in the implementation of IT innovation in the world and a company building customer relations based on the "walled-garden" approach - a case study

Short history

Apple is one of the leading and most valuable companies in the world, which consistently follows the path of permanent innovation, as well as built a leading position among global brands in the electronics industry. The company's activities are focused on both creating new markets and giving value to innovation and a new pace on existing ones. Apple was founded as a result of cooperation between Steve Jobs and Stephen Wozniak. In 1976, both men started their activities in Jobs' bedroom, moving it to the garage. In the same year, a personal Apple I computer was created, which cost 666.66 dollars, and it was produced in 200 copies. A year later, Apple II was created, which was already mass-produced. The successor was easier to use and had more functions. The second model was the basis for education in the 80's and 90's (www.applecenter.pl, 2018). Over the next years, an Apple III computer was created for business, as well as an enhanced Apple IIe and an Apple Lisa computer. Over the last, Jobs did not work, so he took care of the project called Macintosh. These activities, however, were not successful, because the price of the computer fluctuated around 10,000 dollars. Unfortunately, in 1985, Steve Jobs left Apple for 10 years, after a quarrel with another employee. The founder himself had a difficult character, and the crisis in sales caused a violent reaction, so after his departure, Apple was in an increasingly bad financial condition. Subsequent products were not successful and were not popular among customers. In addition, Microsoft released the Windows 3.0 market, which became a direct rival of Apple. The advantage of Microsoft was the fact that the software was compatible with products from various, cheaper manufacturers (Primack, 2011). Apple regained good standing only when Jobs returned as the operations director.

Already in 1998, the founder released a computer that was given the name iMac. On the computer market, it turned out to be a revolution, and moreover, as many as 800,000 iMac computers were sold over 139 days (www.applecenter.pl, 2018). The next steps that Steve Jobs made were: the liquidation of many production lines, leaving only four: a home desktop computer, a professional desktop computer, and portable computers, respectively. Recovering the competitive edge on the market, Jobs's next moves led to additional products bringing huge profits (for example, the breakthrough was the introduction of the legendary iPod in 2001 - it was a portable player with iTunes software, and the user was able to move data freely from computer to iPod and vice

versa). What's more, an online store has been created, from which you can buy different content, which has revolutionized the music industry (Osterwalder & Pigneur, 2010, pp.50-53). Since the return of Steve Jobs, Apple's shares have increased sevenfold. The founder himself did not want to take over any packet of shares. But if he did, after a short time his stock would reach \$ 400 million (Isaacson, 2011). The next big steps Apple made in 2007 launching the first iPhone, and in 2010 the iPad (www.apple.com, 2018). In 2011, Steve Jobs died, leaving Apple with a value of over 300 billion dollars. The power over the company was taken over by one of the trusted employees - Timothy D. Cook, who was responsible for minimizing costs and simplifying production processes (www.applecenter.pl, 2018).

Activity and business strategy of the company towards building relationships with customers

The company deals in the design and production of consumer electronics, software and personal computers. In recent years, thanks to new business models, created in the direction of building a specific culture on the market and innovative rules of competition in the IT industry, Apple has become the most recognized global brand. In reference to the "BRANDZ TOP. 100 most valuable global brands in 2018" the Apple brand is gaining in value both from the investors' point of view and customer experience. It is generally seen that the rise of technology is most apparent in the 12-year change of the Top 10 ranking. All but two brands are technology-related in 2018, compared with only four brands in 2006 (figure 3).

***Figure 3. Top 10 global brands in 2006 and 2018
(Report „BRANDZ TOP....”, 2018, p.22)***

Continuing the overview of the report the creators stated that “leading brands, such as Apple and Amazon continued to raise the bar on expectations for customer experience at every customer touch point—both online and offline—from trial to pick-up or delivery. And brands used more tools, such as augmented reality (AR), to improve the experience. AR software contained on smartphones made it easier for brands to develop relevant AR apps and for consumers to use them. People could shop at furniture stores

like IKEA and view how a particular item of furniture would look in an actual room in their house. Customer experience becomes an even more important driver of differentiation. The challenge for brands was not just to use tools like AR, but to find new, creative, and different ways to use them" (Report, 2018, p.25).

Conclusions and discussions for managerial practice in the area of building customer relations in the IT environment

The technical and technological base of modern platforms and IT solutions indicates the special rank of network models and their usefulness in creating dynamic process structures. Internet as a universal network in connection with the Internet of Things (IoT, IoE) is a technology that changes the perspective of perceiving the world through so-called "datazing", means the ability to collect and store data about "everything, anytime, anywhere" where there is access to the Internet. Thus, the basic canon of the future is the inevitability of the description of each information object (including the client) and the collection and exploration of data in order to discover previously unknown regularities. Connecting more and more devices/sensors to the Internet and using this to monitor their work status gives an idea of the potential of the future use of the Internet in various aspects of managing production, service and marketing processes. Further development of this technology may become the basis for the next dynamization of activities in network models in order to improve the efficiency of business processes (including e-business). The effectiveness of these activities may be directly related to the collection of large amounts of data (the petabyte government) of various stakeholders, including clients and their multi-aspect exploration on-line (Big-Data systems) which may change the level of effectiveness and adequacy of business activities aimed even at the individual customer. Building relationships on the web is an increasingly popular form of contact between the company and the customer due to the technological development of the client himself/herself, who makes purchases online, uses electronic money, and more often transmits information to friends and family electronically than in person, because he/she does not want to waste time or bear costs. Is such a situation conducive to interpersonal contacts? - this question is not the responsibility of today's enterprises, for which an increasing number of transactions counts, not limiting their activities to the chain of stationery stores, because in the first place the speed, efficiency, satisfaction, and trust of the customer to the company count, a good example is Apple.

THE UTILIZATION OF THE HUFFMAN CODE TO IMPROVE MANAGERIAL PERFORMANCE FOR ECONOMIC ORGANIZATIONS USING TOP-LEVEL TECHNOLOGY

Marian Sorin IONESCU

Politehnica University of Bucharest
313 Splaiul Independenței, Bucharest, Romania
marian.ionescu@man.ase.ro

Abstract. *The new challenges arising from the confrontation of the economic organizations with the broadest and complex process generated by modern human civilization, the globalization, the meeting of the needs and desires of the more and more educated end customers, with the skills of use and profound understanding of the new technologies, the responses for vectors of competing economic organizations, require innovative approaches at the level of top organizational decisional-management. In their complexity, the present economic phenomena bring to the human decision an increasing amount of data with particular volumes and structures characteristic of the types of processes represented, so the process of decision making becomes a particularly difficult, interdisciplinary task, the human responsible is required a high standard of professional training. Any economic organization that proposes in its developing strategies to maximize generated added value and profitability, should develop at the level of I.T. compartment policies and methods of prevailing, managing and storing information as effectively and optimally as possible. Compressing this data without losses and preserving its quality is one of the arguments that make the difference in an economy of the successful decisional-management competition. We present in this paper, possibilities of saving the memory spaces allocated to the information used in the operational processes, possibly later extrapolated strategically, with a percentage rate of 20%, up to 90%, depending on the dependence on the type and characteristics of the compressed data in the studied processes. For operational, concrete cases, solutions such as variable length code tables are proposed, thus source code symbols are coded, whose interpretation is essential in developing optimized managerial decision generating organizational performance. In this paradigm of approach, the data used is perceived as character sequences, with the "HUFFMAN Code" algorithm developed, the approach selected in the study is a succession of tabloid structures, is developed step by step, the optimal way of representation to each character as a binary string. For a top organizational decisional-manager this is a competitive alternative in developing an improved, efficient and successful decision-making process. The selected example involves the design of a binary code, in which each character is represented by a string, also binary, unique. The selected operation, a business model used in an economy of performance, substantiates the structures within the "HUFFMAN Code".*

Keywords: Memory Spaces; Compressing Data; Business Model; Binary Code; HUFFMAN Code.

Introduction

Developed on theoretically well-founded principles, they analyze the advantages but also the vulnerabilities induced for this type of alternative approach, of coding, and

finally data compression, using fewer bits than symbols which have a much lower frequency. The efficiency level of this mathematical method, the "*HUFFMAN Code*" method, offers alternatives for efficient implementations, when developing and presenting a linear code, identifiable in a well-defined temporary process, implicitly a sorting process being imperatively developed at input of data. Among the methods that separately encode the symbols used in data processing, the algorithm has an optimality character, but this type of method is not always the optimal choice in the highly diversified portfolio of current data compression methods that are easy to subsequent transpose operationally, is not always the optimal choice.

The present scientific paper, we consider it to be a concrete, pragmatic point of view, with the subsequent possibility of extrapolation, in the case of the practice of the top deciding managers for understanding, modeling, processing, implementing the informational processes, involving a significant number of data, with connotations and valences operational-strategic specific to them. Efficient management, accessibility to the data sequences used, the speed at which such a phenomenon is approached become decisive factors in the hierarchy of business models in a modern business macro-environment, with the totality of its characteristics.

In an economy of competition, the promotion of advanced technologies and avant-garde innovative managerial concepts are vectors for the extensive and intensive consolidation and development of the economic organization in the economic macro - environment. The selection, analysis and understanding of data are fundamental approaches in increasing the performance of the business model selected to be transposed into operability by top decisional management. The value of working with extrinsic informational flows but also intrinsic organizational flows is the factor that delimitates the managerial performance of failure, the key element that provides the competitive advantage, fundamentally the most solid of future success. The lack of development of the informational component within the business model deprives the economic entity of a powerful and aggressive vector of strategic development in well-defined time horizons.

The phenomenology of sampling, optimal analysis and storage of data provides organizational decision makers with the ability to understand the internal operationalization of the business in a multitude of well-defined states over time. Each informational data sequence must be stored, the totality of transactions recorded and ordered according to predefined criteria, thus all the aspects of the data complex are presented in a complete and clear picture to the decision makers and responsible organizational factors, allowing the improving to optimization of the underlying strategies and operationalities. The information must be sorted according to criteria clearly defined by the top decisional-management and registered, the memory space at the economic organization level has a finite capacity, given by the allocated hardware infrastructure, compaction-compression of the data thus becoming an obvious option for the elaboration of a process of generating superior added value, performance of the selected business model, implemented and subsequently operationalized.

The systemic data analysis process is the strategic vector that offers the possibility to identify the most favorable decision for the positive evolution of the economic organization. Data analysis from a conceptual point of view is generally an area of informational science that has become extremely useful in the quasi-totally of the

market segments that make up the modern, globalized and hyper-dynamic business macro-environment. The way of sampling, analysis, sorting, understanding and storage are the factors that condition the present managerial performance but also strategic, on well-defined time horizons, this systemic decision-maker effort provides an exhaustive vision of the entire business. At the same time, it is possible to identify the strengths of the business models, innovative trends and model alternatives, accurately identify the deficiencies and possible directions of model development, changes in strategies and operationality to generate an improving trend towards optimization. In addition to improving and quantifying economic performance by mathematical indicators, data analysis, their compaction and compression, it provides software and hardware facilitation to anticipate and develop predictions regarding the performance of the economic organization in terms of performance, with constraints and rigor of the business macro-environment, as well as internal structural limitations.

The clear and profound understanding of the business model, which elaborates the organizational strategy and the operationalization of the economic entity's activities, is the premise of developing the most correct managerial decisions. The organization's resources at the conceptual software and hardware logistics level require systemic compression-compaction of data processes as viable alternatives to performance identification.

HUFFMAN code

The concept and paradigms that are subsequently positioned make the "*HUFFMAN Code*" an algorithm, a way of compressing data extremely efficient. Approaching the data compression issue for business models is equivalent to implementing a special type of optimized prefix codes, developing the compression process in its entirety does not induce any kind of informational losses. The *HUFFMAN coding* is not conceptually encrypted, this feature is engineered with structure customized and dedicated to operationalized business models, by modifying the *Mainly Mutated HUFFMAN TABLE, MHT*, and *Chaotic HUFFMAN TABLE, CHT* chaotic mass (Atallah, 1999; Cormen, Leiserson & Rivest, 2009).

In systemic data compaction processes used by the top organizational decision management for the elaboration of managerial decision, these are operable with or without losses, including subsequent storage processes admitting successive improvements, at this level some distortions are identifiable. Only certain information has value and influence on the implemented business models, therefore a clear and transparent selection process is absolutely necessary, a relevant amount of data encoded under a particular bits structure is declared to be useful to the intended purpose. In the case of data-loss compaction phenomena, these must be positioned within a tolerated error range such that the re-built replica for the original data sequence does not become a corrupted or false information provider. To select certain types of data compression algorithms, adaptable and useful in understanding, adapting, implementing organizational business models, these are quantified as an initial approach. Concepts such as the operating speed on a certain type of computer, the mathematical complexity of the functional entities that make up the algorithm, the calculation procedures and structures, the amount of data compression and the time allocated for such processes. The similitude degree after the reconstruction of the information from the original, are criteria for choosing data compression algorithms for

economic business organizations. Subsequent distortion of inward data is evaluated using loyalty and informational quality coefficients, the degree of similarity between the reconstructed version and the original sequence of their succession. Systemic data compression and storage phenomena are directly reflected in the analysis and control of organizational strategic operational costs. Thus they identify their value and usefulness of effective elements at the service of the top decisional-management.

The *HUFFMAN code* has a specific "greedy algorithms" structure, the process itself takes place by recording the emergence frequencies of each symbol in a file, and then an optimization process is developed to represent the symbols as a binary string. The fundamental idea of managing information for an economic organization is that of using shorter binary codes. The problem of binary characters code representation ("code", for ease) induces, presents each character as a unique binary string, called "codeword". In the case of a fixed length code, the number of bits which need to be assigned to represent a number of characters is of a very large order. Thus the necessity to enter the variable length code occurs, from our point of view, the most adapted requirements coming from the business environment. The typicality of this new approach is the frequency of emergence of short codeword characters and the rather rare emergence of long codeword characters. Concrete calculations show a 25% saving of memory space allocated within the file used. We only analyze the codes in which code words and a prefix of a certain word code are not identifiable. This concept is referred to in the specialty literature as "prefix-free codes" or in a standard way "prefix-codes".

For economic information used in managerial decision processes concatenation is a process with an improved degree of simplification for any binary code, concatenating codewords defining each character of the storage file. The usage of code prefixes simplifies the reverse process of decoding the information. We find that no wordcode, in operational business practice, is a prefix of another wordcode with which a file begins, the decoding process is unambiguous, not having more interpretations. We identify the initial codeword translated into the original characters, the process is repetitive for the rest of the decoded file. The decoding process requires a conventional representation for a prefix code, the initial codeword can be used easily at any time, the selected binary tree has the characteristics required for such representation. The binary representation for a character codeword is the way, the pattern which needs to be traced from the root of the tree to the character, the truth value "0" involves moving to the lower left branch, the truth value "1" involves moving to the lower right branch. An optimal code for an informational file used by the economic organization admits representation as a complete binary tree, in which each non-final node has two options ("two child branches").

We introduce the formalism in which we consider C as the alphabet for which we use the characters used within the binary tree. All the characters with a certain frequency are positive. It results that the tree for an optimal prefix code has exactly $|C|$ leaf-nodes, one for each letter of the alphabet, exactly $|C| - 1$, internal nodes, after which the search process goes up to the end nodes.

In the practice of the *HUFFMAN code*, management decision at the level of the *I.T.*, department, in order to solve the occurred challenge, the developed model starts with the identification of a T tree corresponding to a prefix code, the development of algorithm and calculation procedures it follows, to quantify the number of bits required

for coding the file in which the information underlying the process is stored and structured.

For each character c in the C alphabet, the $c.freq$ attribute shows the c frequency within the file, let $d_T(c)$ the depth of the "leaf" c within the tree, also to be mentioned that $d_T(c)$ represents the length of code-word for the character selected from the alphabet c . (Cormen, Leiserson, Rivest & Stein, 2009, p.431)

We identify the number of bits needed to encode the file,

$$B(T) = \sum_{c \in C} c.freq \cdot d_T(c), \quad (1)$$

the formula is, from an economic point of view, the value of the binary T tree cost browsing.

Operational implementation, approach through HUFFMAN Code

The algorithm of the *HUFFMAN Code* is a particular case, but from our point of view, flexible and adaptable to business issues, the classic "greedy" type algorithms. Within this algorithm we identify the construction of an optimal code-prefix, which provides exactly the solution and the finality for the complex problem facing the top organizational decisional-management. Considering C selected set with n characters, each character $c \in C$ is a target with an attribute $c.freq$ attached to it, given its frequency of occurrence, the algorithm develops a T - graph tree which corresponds to the optimal coding for a scroll-up process. The process is initiated with the help of a set having the cardinal $|C|$ by the nodes ("leaves") of the graph, going through a sequence $|C| - 1$ of a merging operation leading to the creation of the final tree.

We identify in the implementation conditions of the algorithm the existence of a minimum priority queue, Q ordered by the " $freq$ " attribute, which identifies the objects with the lowest frequency in the merging process.

The result of the development of a merging operational process for business models implemented for economic organizations is the appearance of a new systemic object with an individualized frequency equal to the sum of the frequencies of each of the two objects that participated in the merger phenomenon. An executable pseudocode structure for processes and their transposition into operability previously presented has the structure below.

HUFFMAN calculation algorithm (C)

```

1 → n = |C|
2 → Q = C

9 → return EXTRACT - MINQ
Return the root of the tree

```

(Cormen, Leiserson, Rivest & Stein, 2009, p.431)

Beneficial for the implementation and operational transposition of compression (compaction) of the data used by organizational business models is the development of

possible changes to the *HUFFMAN coding tree*, depending on the main target task. Modeling the Huffman coding tree-specific processes demonstrates that encryption and subsequent data compaction operations are performed only together. The data encoding approach used by the business models specific to economic organizations employs moving processes and algorithms adapted to *HUFFMAN coding*, these are transfers between labeled branches of the tree. Changing the *HUFFMAN encoding tree* structure provides a high degree of compression accuracy of the data used in the decision making process, this has a dual structure, is used in the encryption process (coding), but also in the key switching mechanisms. The process induces a series of multiple mutations, the data streams are shared in segments considered to be representative, "key", depending on the information encoding sequences in the form of representative bit structures.

We note with $T(k)$ the mutations performed in the tree graph level. Each data segment (information) has a number of bits dependent on the number of nodes in the Huffman tree, the segment-level moving process (transfer) is applied to the tree in the case of logical value 1 – "truth", 0 – "false" occurrence, the node is not modified.

The analysis of the proposed Huffman algorithm

The degree of accuracy of the Huffman algorithm, its implementation and operational transposition mode are essential for continuous improvement, up to optimizing business models for economic organizations.

The problem of determining the optimal prefix code has a greedy-type exposure for the data which need to be compacted in the optimal structure, in subsequent mathematical formalisms approached, this approach is detailed.

Observation 1: We consider C a selected alphabet, each $c \in C$ character has an expressible frequency by $c.freq$, considering $x, y \in C$ two characters with the lowest frequency, then there is an optimal prefix code in which the previously defined words, "Codewords" for x, y have the same length, the last bit is the only different element.

Comment: We present a using frequency table of the elements (letters) of Latin alphabet, for data sequences transmitted in English to the studied economic entity (organization), functioning on a particular business model that undergoes a compaction process.

<i>Character</i>	<i>Frequency (%)</i>	<i>Character</i>	<i>Frequency (%)</i>
<i>A</i>	8.167%	<i>N</i>	6.75%
<i>B</i>	1.492%	<i>O</i>	7.51%
<i>C</i>	2.782%	<i>P</i>	1.93%
<i>D</i>	4.253%	<i>Q</i>	0.10%
<i>E</i>	12.70%	<i>R</i>	5.99%
<i>F</i>	2.23%	<i>S</i>	6.33%
<i>G</i>	2.02%	<i>T</i>	9.06%
<i>H</i>	6.09%	<i>U</i>	2.76%
<i>I</i>	6.97%	<i>V</i>	0.98%
<i>J</i>	0.15%	<i>W</i>	2.36%
<i>K</i>	0.77%	<i>X</i>	0.15%
<i>L</i>	4.03%	<i>Y</i>	1.97%
<i>M</i>	2.41%	<i>Z</i>	0.07%

Consider the T tree that represents an optimal code prefix and we modify it to become another optimal code prefix such that the x, y characters appear as adjacent Leaves positioned at maximum depth in the new tree graph, we study whether it is possible to develop a tree for which "codewords" of x and y have the same length, the difference between the two data informational structures is made only by the last bit.

We consider a, b two characters which are Leaves positioned on the same level, "sibling leaves" as depth in the T tree. Without loss of generals, suppose $a. freq \leq b. freq$ and $x. freq \leq y. freq$, until the two values $x. freq$ and $y. freq$ become the leaves positioned with the lowest frequency level, in order, $a. freq$ and $b. freq$ having two random frequencies (arbitrary), in order, result $x. freq \leq a. freq, y. freq \leq b. freq$. There is the possibility of occurrence of the point case, $x. freq = a. freq$ or $y. freq = b. freq$, if the equality $x. freq = b. freq \rightarrow a. freq = b. freq = x. freq = y. freq$, the observation previously presented becomes obviously true.

Scientific analysis continues for $x. freq <> b. freq \rightarrow x <> b$.

A process of changing the location of a and x in the T tree leads to the occurrence of the T' tree, when the position of b and y in the T' tree is changed, the T'' tree is generated in which x, y are "sibling leaves" (the same level of importance) at maximum depth, if $x = b$ but $y <> a$, then the T'' tree x, y does not have "sibling" leaves at the maximum depth in the graph tree, the assumption that $x <> b$, the situation is not likely to occur in the operationalities of the selected business model.

Starting from mathematical relational (1), the cost difference between T and T' trees is:

$$B(T) - B(T') = \sum_{c \in C} c. freq \cdot d_T(c) - \sum_{c \in C} c. freq \cdot d_{T'}(c) = x. freq \cdot d_T(x) + a. freq \cdot d_T(a) - x. freq \cdot d_{T'}(x) - a. freq \cdot d_{T'}(a) = x. freq \cdot d_T(x) + a. freq \cdot d_T(a) - a. freq \cdot d_{T'}(x) - x. freq \cdot d_{T'}(a) = (a. freq - x. freq)(d_T(a) - d_{T'}(x)) \geq 0,$$

because both relationships, $a. freq - x. freq$ si $d_T(a) - d_{T'}(x)$ are non-negative, $a. freq - x. freq$ is non negative because x is the "leaf" of the minimal frequency tree, and $d_T(a) - d_{T'}(x)$ is non negative because a is the maximum depth "leaf" within the T tree.

Analogously it is possible to change $y \rightarrow b$, which does not induce any change in cost, because $B(T') - B(T'')$ is non negative, thus $B(T'') \leq B(T)$.

As long as T is optimal, results $B(T) \leq B(T'') \rightarrow B(T'') = B(T)$, so T'' is an optimal tree in which x, y , appear as "sibling leaves" at maximum depth in the studied tree, which confirms the correctness of the mathematical observation made and the correctness of the developed logical reasoning.

We notice that in compaction of data-information accessed for business models, in order to save and optimally use the used memory space.

The problem of optimal code prefixes is a mathematical property of the optimal graph arborescent substructures. (Cormen, Leiserson, Rivest & Stein, 2009, p.434)

Observation 2: Considering C an alphabet with the $c. freq$ frequency defined for each character $c \in C$, we choose x, y two characters of C with the minimum frequency.

We consider C' to alter the alphabet C in which the characters x, y are displaced and a new character z is added such that the equality $C' = C - \{x, y\} \cup \{z\}$ tooks place, we define $freq$ for C' as for C we identify the mathematical relation $z. freq = x. freq + y. freq$, we consider T' any tree representing an optimal prefix code for the C' alphabet, then the T tree is obtained from T' replacing the "Leaf" node for z with an internal node

having the x, y "children" within the tree-graph structure, this is the representation of an optimal prefix code for the C alphabet.

Comment. It is to be discussed how the cost $B(T)$ of the T tree in terms of the cost $B(T')$ of the T' tree, considering the component costs of equation (1), for each character $c \in C - \{x, y\}$, result the relationality $d_T(c) = d_{T'}(c)$, therefore $c.freq \cdot d_T(c) = c.freq \cdot d_{T'}(c)$ until $d_T(x) = d_T(y) = d_{T'}(z) + 1$, results $x.freq \cdot d_T(x) + y.freq \cdot d_T(y) = (x.freq + y.freq)(d_{T'}(z) + 1) = z.freq \cdot d_{T'}(z) + (x.freq + y.freq)$, from where results:

$$B(T) = B(T') + x.freq + y.freq < - > B(T') = B(T) - x.freq - y.freq$$

Suppose that T is not an optimal prefix code for the alphabet C , then there exists an optimal T'' tree such that $B(T'') < B(T)$, with no generality restriction of the analysis and reasoning developed, T'' have x, y as "sibling leaves". We consider T''' the T'' tree with common parts x, y replaced by the z graph leaf, with $z.freq = x.freq + y.freq$ frequency, results that:

$$B(T''') = B(T'') - x.freq - y.freq < B(T) - x.freq - y.freq = B(T')$$

What reveals a contradiction by subtracting the hypothesis that T' represents a code with the prefix optimal for C' . We conclude that T represents an optimal code prefix for any type of C initially selected alphabet.

Observation 3: The operational callout to Huffman's procedural structure type, generates as an immediate consequence an optimal prefix code (Cormen, Leiserson, Rivest & Stein, 2009).

The operational computing structure for the implementation of the mutational process

The business models for which data is compacted (compressing) using the Huffman code method, are characterized by a variable operating speed of work with the accessed informational structures. The mutation, modification, of the arborescent graph technology using the S.H.T. ("Swapped Huffman Tree Coding"), therefore of transformation-modification of the Huffman codes, for operationalized business models with relative low speeds, is implementable at the level of different algorithms and procedure software, subsequent digitally transposed. The computer structure below is an operational-functional presentation of the mutational process of compaction-compression of data used in the service of business models - the development of top organizational management in the elaboration of the decision

```

OPERATIONAL – FUNCTIONAL STRUCTURE
INPUT: Original – Code, Encryption – Key
char*function mutation
{
    check = maxlenght(OCs);
    while(maxlenght(maked) == check)
    {
        making
        (" ", "0", "1", "00", "01", "11", "000", "001", ...)
    }
}

```

```

        }
        for(i = 0; i < count(maked); i++)
        {
            if((Oc! = maked)or(OC_and maked_is_completely_same))
            {
                that_maked_delete;
            }
        }
        divided Encryption – Key according to count (maked);
        for(j = 0; j < count(maked); j++)
        {
            if(OC_left == maked)
            {
                OC_left's-next = toggle;
            }
        }
        return OC;
        goto NextCode;
    }

```

For a correct understanding of the functioning of the pseudo-code entity, we proceed to a brief description in the structural steps of the previous computer entity. The pursued characteristics are the structure that has been developed, but also its transposition into operationality with the totality of the consequences implicitly derived from it.

- Stage 1 → The coding key is defined in M segments
- Stage 2 → We are in the process of developing a confirmation – verification list
 - "S" of the $T^{(n)}$ tree, $n = \{0, \dots, M - 1\}$
 - The maximum length of each symbol in the checklist is defined
 - $l = k - 1$ bits, k the maximal number of bits from $T^{(n)}$
 - Confirmation – verification list is defined starting from:
 - " " , 0, 1, 00, 01, 10, 11, 000, 001, ... }
 - Confirmation – verification list created, improving it
 - Comparison process with the corresponding tree symbol list
 - Replace Huffman codes with identical ones
 - Or that does not exist in the list of symbols
- Stage 3 → The confirmation – verification list from "Stage 2" is accessed
 - Corresponding to the key encryption segment of "Stage 1"
- Value of 0s in the cipher key segment ignores the mutation, for 1s mutated effected
- Moving verified lists → every symbol belonging to the verified lists
 - M. S. B. = list of the most significant bits, Most Significant Bit
 - Comparison process with the most significant bit $\in$ M. S. B.
- If the symbol is the same, we switch to the next bit in M. S. B., $0 \rightarrow 1, 1 \rightarrow 0$
- Stage 4 → Return to Stage 2 and repeat the process
 - Until the last key segment is reached
 - After generating $T^{(1)}$ we go from step c to stage 2
 - We use $T^{(1)}$ instead of $T^{(0)}$ as a base tree to generate $T^{(2)}$
- Repeat process until the end segment of the cipher key is reached

Redundancy of Huffman codes, main results

The enormous amount of information with which the selected business model is confronted within the macroeconomic environment, makes the sorting processes and its subsequent compression to store two fundamental choices for achieving the highest added value and generating organizational performance. The Huffman codes are subjected to a redundancy of a certain intensity; their subsequent operationalization is conditioned by solving this type of challenge. Scientific studies show that a characteristic of Huffman codes is the existence of a relatively "tight" upper limit, the lower limit of this process of data compression resulting from derivation.

We consider a non-memory source S to belong to a finite N dimensional alphabet, of the structure $S = \{s_1, \dots, s_N\}$ and a multiple set of probabilities, which may contain repeating members due to different source symbols but with equal probabilities, $P = \{u_1, \dots, u_N\}$, $u_i \Pr(S = s_i)$.

A source code with the variable length D for the S source is defined by the one-to-one coding function, $f_C: S \rightarrow \{0, 1, \dots, (D - 1)\}$, thus we can calculate the average length of a code, C specific to the compression Huffman processes with

$$L(C) := \sum_{i=1}^N u_i l_C(u_i) \quad (2)$$

One of the fundamental goals pursued in data compression processes for business models is that of developing minimal length codes, the average minimum length of a code without prefix cannot be less than the entropy source, regardless of the degree of code efficiency, the entropy in the base D is represented by the symbolism

$$H(S) := - \sum_{i=1}^N u_i \log_D(u_i) \quad (3)$$

an important indicator of quantification of source code performance is redundant, redundant is the difference between the mean length and the entropy of the informational source (of data), expressible by

$$R(C) := L(C) - H(S) \quad (4)$$

The Huffman coding algorithm and data compression algorithm provides an optimal prefix code for a memory-free source of information, no code for the P distribution can not have a shorter length than the Huffman code. (Cormen, Leiserson, Rivest & Stein, 2009; Dasgupta, Papadimitriou & Vazirani, 2008; Lewis & Papadimitriou, 1998)

A D – Huffman code is represented by a $D - T$ tree whose leaves are the correspondence of the source symbols, the sides of D that go from each intermediate node of T are labeled with one or more D -sides of the previous presented alphabet, the word code is the "codeword" corresponding to the symbol is the (indefinite) label vector positioned along the path from root to leaf in the corresponding tree graph. Thus, we identify the situation where, for selected organizational business models, Huffman's compaction-compression data algorithm is a functional recursive bottom-up construction of T , where at each step of D there are nodes with the least probability combined in a new node, thus adding a number of symbols from an inactive source having zero probability. The number of N source symbols is expressed in mathematical form $k(D - 1)$ for k integer, from now on they represent intermediate nodes in the tree.

In the majority of applications of the economic models, Huffman's operationalized codes are binary type, $D = 2$, Huffman's redundancy within the used business model analysis

is always non-negative, but neither exceeds numerical value 1. The upper limit of $R(T)$ redundancy by addressing binary Huffman codes when $p_1 := \max_i u_i$ and u_i correlates with the probability that the most commonly used symbol of the source is known. The problem of the superior margin of redundancy in probability terminations in mathematical formalism $p_N := \min_i u_i$. The probability that the smallest operationalized symbol of the source is known, the upper margin, $R(T)$ in the case of the Huffman type codecs, is well defined when both probabilities for extremes p_1 and p_N are known. The upper limit of the redundancy margin is derived from a function having the probability conditioned by the two source symbols p_{N-1} and p_N .

In the following is presented a well-controlled upper limit of the redundancy addressed with the help of Huffman codes, for a source that contains a symbol with a certain given probability p .

Observation 4: We consider a Huffman code for a finite alphabet source, that includes a symbol with the probability p , otherwise being arbitrary.

Redundancy of this code is superior to

$$R_{\max}(p) := \begin{cases} 2 - p - H(p), & \text{daca } 0.5 \leq 1 < 1 \\ 1 + p - H(p), & \text{daca } 0 \leq p < 0.5 \end{cases}$$

where $H(p) := -p \log p - (1 - p) \log(1 - p)$ is a binary entropy function, the relation shows a strong interconnection, so are identifiable distributive sequences whose redundant Huffman converge to the value $R_{\max}(p)$.

This observation shows the superior margin in the case of Huffman redundancy.

Observation 5: We consider the Huffman code for a finite alphabet source, which includes a symbol with the probability p , otherwise being arbitrary.

Redundancy of this code is inferior limited by

$$R_{\min}(p) := mp - H(p) - (1 - p) \log(1 - 2^{-m})$$

where $m > 0$, let the value $[-\log p]$ or $[-\log p]$ which minimizes expression, we identify the interconnection between the distribution source of the symbol having the probability p with the Huffman code redundancy equal to $R_{\min}(p)$.

Observation 6: The redundancy of a Huffman code D – set contains a letter with probability p has a "tightly" limitation, computable by

$$R_{\min,D}(p) = mp - H_D(p) - (1 - p) \log_D(1 - D^{-m})$$

Observation 7: We consider p the characteristic probability of any source symbol, then the corresponding redundant for the upper margin of the Huffman code is

$$R_{ub} := \begin{cases} 2 - p - H(p), & \text{daca } 0.5 \leq p < 1 \\ 0.5, & \text{daca } \pi_0 < p < 0.5 \\ 1 + p - H(p), & \text{daca } p \leq \pi_0 \end{cases}$$

we note that $\pi_0 \cong 0.18$ is the smallest root of the equation $1 + p - H(p) = 0.5$

The calculation of the superior redundancy for a known probability source is one of the concerns that influence the phenomenology approach of compressing-compaction data with the help of Huffman code methodology.

Observation 8: Considering p_1 the symbol probability of the most known source, the Huffman redundant of this source is superior margined by the function

$$f(p_1) = \begin{cases} 2 - p_1 - H(p_1), & \text{daca } 0.5 \leq p_1 < 1 \\ 3 - 5p_1 - H(2p_1), & \text{daca } \pi_1 \leq p_1 < 0.5 \\ \gamma, & \text{daca } p_1 \leq \pi_1 \end{cases}$$

where $\gamma = R_{\max}\left(\frac{1}{3}\right) = 1 + \frac{1}{3} - H\left(\frac{1}{3}\right) \cong 0.415$, $\pi_1 \cong 0.491$ is the root of $3 - 5x - H(2x) = \gamma$

Observation 9: If p_1 is the probability of a letter in a source, if its value $p_1 \geq 0.4$, then the length corresponding to the codeword in the Huffman coding approach is one that satisfies the condition $l(p_1) = 1$. (Dasgupta, Papadimitriou & Vazirani, 2006)

Conclusions

Modern economic organizations, actors in the modern economic macro-environment, regardless of the strategic operational business model selected, are confronted with an enormous amount of data, these coming from the intrinsic but especially the extrinsic economic entities. Relevant conducted business activity information needs to be sorted, analyzed, interpreted and subsequent transposed into arguments for the taken decisions. The programs for encryption, compression and storage of data useful to top organizational management are conditions, facilities that make the most of generating added value, sustainable growth vectors in modern, globalized, and particularly dynamic economic competition. The Huffman coding and compression algorithms do not induce data loss at file level, thus the organizational economic history is not affected, the determining role in their operational transposition is the frequency of the occurrence of a symbol in the compression file.

Statistical coding is fundamental to the usage of the Huffman algorithm in the complex economic issues, therefore the probability of symbols has a direct influence on the length of its representation, the more probable the occurrence of a symbol, the shorter the representation of the bits sequence. Comparing with other types of approaches, A.S.C.I.I. coding, for example, fixed length code, the Huffman encoding is a variable length system, assigns smaller codes for characters with a high degree of usage, smaller codes for less frequently used characters, thus the files are reduced and the data transfer process is much simplified.

Several studies (Lewis & Papadimitriou, 1998). Economic competition, strengthening and developing the position of the economic organization in the specialized market, where it is an actor, becomes in the digital age a competition for the understanding, analysis and operational transposition of the information. Organizational software and hardware structures are active parts of the systemic process to achieve economic performance through correct, optimized managerial decisions.

Huffman's data compression methods are a fundamental argument in achieving these central targets, as well as fundamental research trends, subsequent applicative transposition and quantification in increasing profit returns demonstrating their importance.

Abstract. *The purpose of this paper is to determine the differences between companies and customers from the perspective of using social media networks. Social media networks have a tremendous potential in terms of bringing the companies closer to customers. Through social media, consumers can interact with businesses to get the value they are looking for, whether we are talking about discounts or specific information. Unfortunately, not all companies are aware of customers' needs and do not properly use social media networks to facilitate experiences and collaborative dialogue that customers value. In this regard, the authors used a questionnaire containing 11 items that can be divided into 4 sections: social media networks used by employees and customers, employees' perceptions about the reasons consumers interact with companies via social media, the reasons employees think companies interact with customers via social media, social media networks used by companies to interact with customers for different reasons. Data were collected from a group of engineers who graduate from Politehnica University of Bucharest and who work for companies from different domains. Then, data were statistically analyzed using SPSS 20.0 Software. The conceptual framework contains 3 variables: Customers' reasons for using social media, Companies' reasons for using social media, and Social media networks, each being defined through different items. Our findings indicate that Facebook and LinkedIn are the internet users' favorite platforms for interacting with companies or customers, while unlike other countries, Twitter is one of the social media networks used very little by internet users from our country. The results pointed out that there are positive moderate correlations between why consumers use social media for seeking information and why companies use social media for marketing and social interaction. There are also positive moderate correlations between companies' and consumers' reasons for using social media for communication, and also between why companies use social media for their development and why consumers use social media for improving services/products offered by a company. The results of our study should be interpreted with caution, this study being an exploratory one, with a few limitations. Only the perceptions of the people surveyed have been considered. The people surveyed played a double role in our study: customers who use social media and employees who are working in companies that use social media. Therefore, in the future, the authors want to reconsider studying companies' reasons for using social media by analyzing the managers' responses that are responsible for marketing and online marketing in organizations.*

Keywords: *social media; social media marketing; social networks; social media usage; Web 2.0; organizational innovation.*

Introduction

Social media has started to evolve into a necessary part of our society. According to The Statistics Portal (2018), in the last 6 years, the number of minutes spent on social media by internet users worldwide increased by 50%, daily media usage of social media users being 135 minutes per day. By making a simple calculation, it can be said that an internet user spends an average of 821 hours per year with social media. Furthermore, in 2016, there were more than 2 billion social users all over the world.

Taking into account these statistics and trends, companies have also begun to use social media and its various tools found in this area in order to be as close as possible to users. Thanks to social media, companies can improve customer relationships which allow them to gather more information about customers and adapt their services/products according to the demand. Also, by using social media, companies can increase their brand awareness, a larger audience meaning more potential customers. Unfortunately, not all companies know how to use social media networks to their own advantage, and the time they spend on this activity is wasted in vain. They need to do more research on social media networks, about their customers' needs, then they should establish a strategy and implement it without compromise.

The purpose of this paper is to determine how aligned companies and their consumers are in their intentions when communicating on social media. The authors investigate whether there is a perception gap between the reasons consumers interact with companies via social media and the reasons businesses use social media in their interactions with customers.

Theoretical backgrounds

In the last decade, social media has entered the marketing and communication mix of companies, its transformation being extremely dynamic. Businesses of all sizes have boosted marketing through social media platforms and their number has increased from year to year.

As indicated by Safko (2010), social media is a collection of sites that are used for communication and social interactions by millions of people from all over the world, but also to reach targeted audiences. Through these social media networks, platforms and tools, internet users can publish or share different type of content (text, photos, videos, music), using as well different functions such as multiplayer games, review of purchases, shopping online, recommendation, event locations, and personal, professional or informal social networks (Cavazza, 2012). Also, Kaplan & Haenlein (2010) defined social media as "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user-generated content".

Social media facilitates the communication between internet users and between customers and companies that use social media networks, tools or platforms available on the Internet. Social media has reinvented the ways organizations relate to the economy and society, improving various parts of a business, from marketing and operations to finance or human resource management (Aral et al., 2013).

Social media utilization is a popular research topic, with almost 200,000 results on Google Scholar targeting the last five years. According to de Araújo & Zilber (2016), using social media networks can alter the relationship between companies, their employees, suppliers, customers, and other partners, and also their relationship with people from outside the companies who want to interact with them as job candidates, potential customers or partners.

There are some studies that demonstrate how social media positively influences organizational innovation or organizational performance (Garcia-Morales et al., 2018; de Araújo & Zilber, 2016; Kärkkäinen et al., 2010; Hartono & Sheng, 2016; Palacios-Marques et al., 2015) or studies that analyze how social media influence the customer relationship component (Baird and Parasnis, 2011). Kärkkäinen et al. (2010) presented in their paper that social media can be used by companies for: branding, information sharing, public relations, understanding customers, lead generation, collaborative work, internal communication, sales support. De Araújo & Zilber (2016) mentioned that the relative advantages of using social media can be represented by: improving exposure to the company's brands/products, differentiating the company from its competitors, increasing company revenues, operating in unexplored market niches, improving customer, employee, and supplier relationships, the process of hiring new employees and also increasing the amount of information provided to customers about the products marketed.

In Romania, there are few studies about social media and their degree of usage in companies. According to The Like & Share study - Social media marketing in Romanian companies 2017 (Valoria, 2017), social networks are used by Romanian companies mainly for communication (90%), marketing (75%), sales (39%). Although at some distance, 35% of companies use social networking for recruitment, 32% for customer relations, 27% for research, and 25% for competitive analysis. The most used social media marketing platforms in Romania are: Facebook - 96%, LinkedIn - 70%, YouTube - 44%. The top three places worldwide are: Facebook - 93%, Twitter - 76% and LinkedIn - 67%, both Facebook and LinkedIn having higher usage percentages in Romanian companies than globally.

Another study made by Ernst and Young Romania (2015) analyze the answers of some company representatives from various industries in Romania about how they approach marketing through social networking and the impact that this type of marketing currently has on their work.

In the specialized literature there are also some studies about why consumers use online communities (e.g. Koh et al., 2007; Wiertz & de Ruyter, 2007; Sledgianowski & Kulviwat, 2009). Sledgianowski and Kulviwat (2009) found that playfulness and critical mass attract consumers most, Dholakia et al. (2010) discussed about the consumers' benefits of using social media, while others tried to identify the impact of new media on customer relationships (Hennig-Thurau et al., 2010).

Whiting and Williams (2013) mentioned that customers use social media in their interaction with companies for seven reasons: social interaction (communicate and interact with others); information seeking (seek out information or to self-educate); pass time (occupy time and relieve boredom); entertainment (provide entertainment and enjoyment); relaxation (relieve day-to-day stress); communicatory utility

(communication facilitation and providing information to share with others) and convenience utility (providing convenience or usefulness to individuals).

Baird and Parasnis (2011) identified that companies have some misperceptions regarding why consumers interact with them via social sites. For example, their findings show that most of the customers use social media when they interact with a business for “getting discounts or coupons”, “purchasing products and services” and “reading reviews and product rankings”. In contrast, those three activities were at the end of the reasons list that companies believe customers use social media for their interaction. Taking into account the information found in the analyzed studies, the authors decided to determine the differences between companies and customers from the perspective of using social media networks. In this regard, the authors wanted to answer to the following questions:

Q1: What are the most used social media networks by the consumers and employees from Romania?

Culnan et al. (2010) presented in their paper that Twitter, Facebook and blogs are the most popular social media platforms used in the US by companies that were presented in Fortune 500's top. Thus, the authors are looking to see if these three social media platforms were also the most used in Romania by both consumers and employees.

Q2: What are the most used social media networks by the consumers and employees from Romania for: seeking/providing information, social interactions, company development, marketing, promotion, relaxing, entertainment, communication?

After they will gather information about what are the most used social media platforms, the authors' target is to verify if there is a dominant platform that is used for some different reasons by the Romanian internet users.

Q3: Why consumers use social media in their interaction with companies?

In order to get an answer for this question, the authors measured the consumers' perceptions about seeking information, social interactions, company development, marketing, promotion, relaxing, entertainment and communication in relation to social media usage.

Q4: Why companies use social media in their interaction with customers?

In this case, the authors measured the employees' perceptions about why they think companies that hired them use social media. The following factors can be: help their customers with providing information, making social interactions, communicate, getting entertained, contribute to the development of the company or be closer to it.

Conceptual framework

The aim of this paper is to analyze the perception gap existing between the reasons consumers interact with companies via social media and the reasons businesses use social media.

The conceptual framework is presented in Figure 1, which shows the customers' and companies' reasons for using social media networks. In this study, we identified three variables. Customers' reasons for using social media can be defined through the following items: seeking information; buying new products/services; communication; relaxing, entertainment; social interactions. The construct Companies' reasons for using social media can be defined through the following items: providing information; marketing, special offers; communication; company development; relaxing, entertainment; social interactions.

Figure 1. The consumers' reasons vs. companies' reasons to use social media networks

Research design and methodology

The research in this paper was an exploratory one in order to have an overview of the perception gap existing between the reasons consumers interact with companies via social media and the reasons businesses use social media when they want to interact with them.

In this case, the authors used the respondents' perceptions. The respondents played a double role. First, they were considered customers who interact with companies, and then they were considered employees of the company where they were working in order to present the companies' reasons for using social media with customers' interactions.

For collecting the data, the authors used a questionnaire containing 11 items that can be divided into 4 sections: social media networks used by employees and customers, employees' perceptions about the reasons consumers interact with companies via social media, the reasons employees think companies interact with customers via social media, social media networks used by companies to interact with customers for different reasons.

For this study, during June 2018, the authors collected data from a group of engineers who graduate from the Faculty of Entrepreneurship, Business Engineering and Management from University POLITEHNICA of Bucharest. The majority of the respondents work in companies with more than 250 employees (43.2%), while 61.4% of these companies are founded at least 10 years ago. This study is an exploratory one,

the number of respondents for this analysis being 44, 79.5% of the respondents being very familiar with the term “social media”.

Variable measurement

The authors identified 34 variables that can be divided into 4 sections (as it can be seen in Table 1), each variable receiving a code name (CN). Constructs from Sections 3 are defined later in Table 2.

Table 1. Identified variables and their codes

Section 1		Section 2		Section 3		Section 4		Section 5	
Variable	CN	Variable	CN	Variable	CN	Variable	CN	Variable	CN
Knowing the term “social media”	SM	Consumers’ perception- Seeking information	RA	Employees’ perception- providing information	FRA	Social media used by company for Providing information	ChR1	Age of the company	Age
Social media used by respondents	SMR	Consumers’ perception- Marketing, promotion	RB	Employees’ perception- Marketing, promotion	FRB	Social media used by company for Marketing, promotion	ChR2	Number of employees	NrE
The most used Social media network by respondents	USM	Consumers’ perception- Communication	RC	Employees’ perception- Communication	FRC	Social media used by company for Communication	ChR3	Domain of company	D
Social media used by company	SMC	Consumers’ perception- Company development	RD	Employees’ perception- Company development	FRD	Social media used by company for Company development	ChR4		
		Consumers’ perception- Relaxing, Entertainment	RE	Employees’ perception- Relaxing, Entertainment	FRE	Social media used by company for Relaxing, Entertainment	ChR5		
		Consumers’ perception- Social interactions	RF	Employees’ perception- Social interactions	FRF	Social media used by company for Social interactions	ChR6		

In section 1, the authors identified what is the people’s surveyed level of knowing the term “social media” (SM), what social media platforms are used by respondents (SMR), what is the most used social media platform by consumers when they interact with a company (USM), what is the most used social media platform by companies when they interact with a customer (SMC). For section 2, the authors analyzed the main reasons a respondent use social media for his interaction with a company, while in section 3 the authors analyzed the employees’ perceptions about why companies use social media when they interact with customers. In section 4 were identified the most used social media platforms by companies for different reasons. In the last section, the authors have analyzed three control variables (age of the company where the respondent works, the number of employees of that company and the domain where the company operates).

Table 2. Identified variables from Section 3 and their codes

Variable	Code	Final Code
Provides information about companies, products, services	A1	$FRA=(A1+A2+A3)/3$
Provides information about companies' promotions	A2	
Provides information about companies' events	A3	
Job offers	B1	$FRB=(B1+B2)/2$
Brand awareness	B2	
Sharing information, reviews	C1	$FRC=(C1+C2+C3)/3$
Suggestions	C2	
Complaints and check statuses	C3	
Customer loyalty and sales growth	D1	$FRD=(D1+D2+D3)/3$
Developing new partnership	D2	
Differentiation from competitors	D3	
Relaxing, entertainment	E	$FRE=E$
To be informed about companies' concerns	F1	$FRF=(F1+F2+F3)/3$
To be informed about consumers' concerns	F2	
To be informed about employees' concerns	F3	

A part of these reasons were taken and adapted from Whiting and Williams' study (2013), Baird and Parasnis' paper (2011) and others from de Araújo and Zilber (2016) (who presented some indicators for the variable Relative Advantage that defines Perceived Innovation Characteristics of a company in their paper). The authors used the most known social media networks, where a part of them were identified in a study made in 2015 by Ernst &Young Romania.

For this study, the authors averaged variables identified in section 3 in order to obtain a value for each main reason a company uses social media in order to be in touch with customers. Most of the variables were measuring perceptions of the people surveyed. For the variables identified in section 2 and 3, the items were measured on a 5-point Likert-type scale ranging from 1 (never) to 5 (always).

Results and discussions

All measurements were based on the respondents' perceptions, while data was analyzed using SPSS 20.0 software. First, the authors identified the most used social media networks by companies. As it can be seen in Table 3, 81.8% of the analyzed companies are using Facebook, 45.5% are using LinkedIn, 43.2% WhatsApp and 31.8% Skype.

In Table 4, the authors presented the social media platforms that are used often by users when they want to interact with a company. From this point of view, it seems that LinkedIn is the internet users' favorite platform for interacting with an organization (36.4%) followed closely by Facebook (34.1%). Also it seems that 11.4% of the people surveyed still use the companies' official site for any interaction to the detriment of social media networks.

Table 3. Social media platforms used by companies in relation with internet users

Facebook (%)	Twitter (%)	Instagram (%)	Skype (%)	YouTube (%)	LinkedIn (%)	Hangouts (%)	WhatsApp (%)	Blog (%)
81.8	18.2	25.0	31.8	27.3	45.5	2.3	43.2	18.2

Table 4. Favorite social media platform used by customers in their interaction with companies

Facebook (%)	Twitter (%)	Instagram (%)	YouTube (%)	LinkedIn (%)	Blog (%)	Official site (%)
34.1	2.3	6.8	2.3	36.4	6.8	11.4

Another aspect tested by the authors was to determine if there is any correlation between the reasons customers interact with companies via social media and the reasons businesses use social media (Table 5), using the interpretations for R-values suggested by Evans (1996).

Table 5. Correlation matrix among main variables

	RA	RB	RC	RD	RE	RF	FRA	FRB	FRC	FRD	FRE	FRF
RA	-											
RB	.572**	-										
RC	.409**	.302*	-									
RD	.112	-.033	.528**	-								
RE	.379**	.375*	.297*	.039	-							
RF	.513**	.505**	.372*	.243	.651**	-						
FRA	.353*	.137	.384**	.306*	.133	.178	-

FRC	.198	.114	.418**	.356*	.041	.252	.683**	.430**	-			
FRD	.206	.103	.341*	.425**	-.029	.248	.590**	.376**	.727**	-		
FRE	.101	-.130	.109	.323*	0	.013	.660**	.443**	.554**	.591**	-	
FRF	.401**	.081	.247	.212	.120	.236	.720**	.487**	.695**	.664**	.603**	-

Note. N=44; *p <0.05, **p<0.01

As it can be seen in Table 5, there are some moderate positive correlations across consumer and company uses of social media as follows:

- R=0.521 (p<0.01) between consumer use of social media to seek information (RA) and company use of social media for marketing (FRB);
- R=0.406 (p<0.01) between company use of social media for marketing (FRB) and customer' desire of using social media for buying new products/services (RB);
- R=0.418 (p<0.01) between using social media for communication by consumers (RC) and companies (FRC);
- R=0.425 (p<0.01) between companies use of social media for their development (FRD) and customers use of social media for improving services/products offered by a company (RD);

- $R=0.401$ ($p<0.01$) between customers use of social media for seeking information (RA) and companies use of social media for social interaction (FRF).

It can be seen that, between some variables which describe the reasons companies use social media, there are strong correlations that are significant at 0.01 level (2-tailed), like:

- $R=0.675$ between providing information (FRA) and marketing, promotion (FRB);
- $R=0.683$ between providing information and communication (FRC);
- $R=0.660$ between providing information and relaxing, entertainment (FRE);
- $R=0.720$ between providing information and social interactions (FRF);
- $R=0.727$ between company development (FRD) and communication (FRC);
- $R=0.695$ between social interactions (FRF) and communication (FRC);
- $R=0.664$ between social interactions (FRF) and company development (FRD);
- $R=0.603$ between relaxing, entertainment (FRE) and social interactions (FRF).

Those strong correlations can be explained by the fact that companies already have some goals for their development and those goals are interdependent. When companies decide to use social media, they also adapt their goals, but they have in mind the main aim of their existence: profitability. This profitability can be achieved only if customers are happy with their interaction with the firm.

After that, the authors wanted to establish what social media networks are used the most by the companies where the respondents were working for the following reasons: providing information, marketing, promotion, communication, company development, relaxing, entertainment, social interactions.

According to our results (Table 6), Facebook is the most used social media network for all of the reasons mentioned before. This network is especially used for marketing, promotion (81.82%), providing information (75%), communication and social interactions (63.64%). It is important to highlight that Google Hangouts is used in a proportion of 27.27% for company development.

Another aspect treated by the authors was the frequency of using social media networks by the customers or by the companies for the main reasons identified before in this paper. In Table 7 it can be observed that customers use social media to interact with companies to seek information (45.5%), to buy new products/services (63.6%), for communication (54.5%), entertainment (56.8%) and social interactions (50%), but they do not really use social media for company development (for example by offering suggestions or recommendations about the company's products or services).

Table 6. Social media networks used by companies and the reasons of their using

	ChR1	ChR2	ChR3	ChR4	ChR5	ChR6

Always	9.1	29.5	25.0	4.5	25.0	20.5

Table 8. Frequency of using social media networks by companies for different reasons

Frequency of using social media networks	Companies' reasons of using social media networks														
	Providing information (%)			Marketing. Promotion (%)		Communication (%)			Company development (%)			Relaxing. Entertainment (%)	Social interactions (%)		
	A1	A2	A3	B1	B2	C1	C2	C3	D1	D2	D3	E	F1	F2	F3
Never	0	2.3	13.6	2.3	0	9.1	4.5	15.9	9.1	11.4	4.5	9.1	4.5	4.5	6.8
Rare	4.5	4.5	15.9	9.1	4.5	11.4	22.7	13.6	13.6	20.5	15.9	18.2	27.3	6.8	13.6
Sometimes	25.0	13.6	22.7	27.3	15.9	29.5	25.0	27.3	34.1	27.3	25.0	25.0	34.1	45.5	43.2
Frequent	27.3	43.2	22.7	22.7	15.9	25.0	29.5	22.7	22.7	22.7	31.8	31.8	18.2	18.2	11.4
Always	43.2	36.4	25.0	38.6	63.6	25.0	18.2	20.5	20.5	18.2	22.7	15.9	15.9	25.0	25.0

Besides, looking at our results about companies' reasons of using social media networks for their interactions with customers (Table 8), we can see that for almost every reasons identified, the companies try to use social media network as often as they can, focusing on brand, products and services promotion (always- 63.6%). It is curious to see that companies not really use social media to be informed about other companies' concerns

(at least frequently- 34.1%), customers' concerns (at least frequently -43.2%), employees' concerns (at least frequently- 36.4%) or to develop new partnerships (at least frequently- 40.9 %) and they rarely provide information about companies' events or parties (29.5%).

Discussions and conclusions

This study presents the differences between companies and customers from the perspective of using social media networks. The results pointed out that Facebook and LinkedIn are the internet users' favorite platforms for interacting with companies or customers, fact that has also been demonstrated in Valoria's study from 2017. On one hand, Facebook is the most used social media networks, being well known by the internet users and also publicly advertised such as in TV commercials. On the other hand, LinkedIn is the professional platform that someone uses when it comes to more serious and official things about the possible partnership between customers and companies.

According to our findings, there are some positive moderate correlations between identified reasons, like those between why consumers use social media for seeking information (RA) and why companies use social media for marketing (FRB) ($R=0.521$, $p<0.01$) and social interaction (FRF) ($R=0.401$, $p<0.01$).

Companies should track Google Trends and social platforms to identify the most popular information searched by customers and check through market research or case studies what are the customers' needs in order to improve the company's marketing strategies or their social interactions with the clients. If companies are concerned about these issues, then customers will use social media platforms more often to look for information about products, companies, events, or available jobs.

Furthermore, there are some positive moderate correlations between using social media for communication by consumers (RC) and companies (FRC) ($R=0.418$), using social media by companies for their development (FRD) and using social media by customers for improving services/products offered by a company (RD) ($R=0.425$), all the mentioned correlations being significant at 0.01 level (2-tailed).

On one hand, companies can use social media to attract customers, to develop new partnerships or to differentiate themselves from competitors, all of these activities contributing to the development of the company, which is also stimulated by the use of social media platforms for purchasing new products or services.

On the other hand, through social media platforms, customers can read or provide reviews of companies' products or services, express their opinions on how to improve existing products or services, which the company can use to develop it. In addition, if companies want to develop themselves through social media, they should organize various contests to stimulate their clients to participate in the company's development process. Thus, the communication between companies and customers will be improved. Our study is an exploratory one, with a few limitations. First, only perceptions of the people surveyed have been considered. The people surveyed played a double role in our study: customers who use social media and employees who are working in companies that use social media. Therefore, in the future, the authors want to reconsider studying

companies' reasons for using social media by analyzing the managers' responses that are responsible for marketing and online marketing in organizations.

Second, the sample was represented only by 44 people, which is why in the future, the authors want to conduct a more elaborate study, on a much larger national sample in order to see if the differences between companies and customers from the perspective of using social media networks will be the same as those identified in this study.

By taking into account the issues presented, companies should carefully consider their social media experience and adapt their every social media network to the needs and preferences of their targeted internet users. In order to do that, companies should start with recruiting digital marketing managers with experience or at least with starting to think like a customer. If companies knew why and how a potential customer uses social media to facilitate their interaction, then they could adapt their strategies to focus on giving customers the value they seek. More important than that, if companies do not know what are the most important things for customers, then they should ask them, making them feel important and contribute to developing new ideas, processes, products or services. Future studies look to present more in-depth recommendations for companies so that they align with their customers' needs when engaging with them on social media.

Abstract. *The paper presents some characteristics of the ways online social networks influence the selection of online shopping websites. This research aims to identify the factors that lead to the behavior of searching for information on online social networks when considering to buy a product or a service online, specifically to identify the roles of trust, community commitment, and perception of member affiliation (we-ness) in the decision-making process. As most research papers in the e-commerce field analyzing the factors that influence purchase behavior, this paper uses a quantitative research method, the questionnaire, which was applied in May 2017. The research sample consisted of 166 Facebook users. Facebook is representative considering the large number of users and the amount of time spent on this social network. All of the participants are students at the College of Communication and Public Relations, at the National University of Political Studies and Public Administration, from Bucharest, aged between 18 and 24 years old. The research results revealed that there is a relationship between propensity to trust community members and seeking information on online social networks, even though users are not highly trusting online social networks. According to the results, the Facebook community represents an important source of information where the users have the possibility to consult details, opinions, reviews related to online shopping experiences, but the attachment to the community is to a low degree. The participants from our study mostly use Facebook as a space for obtaining the relevant information for their intention to buy specific products or services, passively consuming the content from this channel. These findings suggest the importance of online shopping websites to communicate on online social networks, where individuals gather information in their intention and selection process of online buying.*

Keywords: *online shopping; information seeking; online social networks.*

Introduction

The growing number of online users and the development of applications that are designed to develop habits (Eyal, 2014) represent just some of the factors that

encourage businesses to engage in e-commerce or e-sales in general. According to Eurostat's study (2017), one out of five EU-28 enterprises conduct electronic sales, with rising figures annually. The wide-spreading e-shopping is common among all age groups, as the numbers in 2016 demonstrate: the highest share of EU e-shoppers is represented by users aged between 25 to 34 (75%), followed by 35 to 44 (69%) and 16 to 24 (68%) (Eurostat, 2016). According to GPEC (2017), 44% internet users shopped online at least once a month, and 62% of these users are aged between 18 to 34. Romanian online shoppers visit 9 online stores per year with a frequency of 3 or 4 times per week, suggesting that the interest and information seeking behaviors are present on an ongoing basis.

While social media applications offer businesses the possibility to connect and deliver their message to a large pool of users (Kietzmann et al., 2012), or to promote products and build reputation (Broekemier, Chau & Seshadri, 2015), the effort of gaining user attention to various products and services represents a consistent endeavor. Only some studies have been focusing on investigating user behavior on online social networks and the factors enhancing or relating to purchase decisions or intentions (Mahrous, 2015, Mahrous & Abdelmaaboud, 2017). Elsharnoby and Mahrous (2015) identified users' tendency to use social media as a primary source of information before making a purchase, which is evident considering the interactive platforms that allow asking questions, posting answers and evaluating users in the same time. By considering the comments posted by other users, the potential consumer's behavior can be influenced (Kannan & Hongshuang, 2017). The affiliation of members inside a virtual community has been found to represent an important factor when engaging in this space of interaction (Fayard & Metiu, 2013), while the trust was identified as a factor increasing purchasing decisions when social commerce is concerned (Farivar, Turel & Yuan, 2017). But further research is needed in order to develop a more thorough approach to the antecedents of information seeking behavior. Therefore, the following research questions were established for the purposes of this research:

RQ1. Which are the *factors* that influence users in the online buying process?

RQ2. What is the relationship between the *propensity to trust*, the *perception of member affiliation (we-ness)*, *community commitment*, *trust in online shopping*, and *online social network consulting*?

RQ3. What is the relationship between the *propensity to trust* and *information seeking* on online social networks?

Theoretical background

Advantages and challenges of online shopping websites

Online users have access to many online sources that assist them in becoming informed consumers. They have access to information related to costs, characteristics, quality, replacement options, ease of delivery and shopping experiences of other users. As Kotler (2009) stated, the consumer is the one controlling the interaction, and not the seller (p.325). Specifically, online marketing allows (1) potential buyers to advise with the shopping website in taking the best decision possible, (2) to access information fast, especially information that favors the business in comparison with other businesses, and (3) to make the purchase in a timely manner, as even automatic sales agents can assist the buying process smoothly. Utilitarian value including saving time, the cost of

searching for products and services, purchasing efficiency represent the primary advantages of choosing online shopping (Chang et al., 2015).

Besides advantages, consumers can also encounter challenges in the buying process. Studies have shown that challenges specifically include safety of electronic transactions and payment security systems (Liao & Cheung, 2001; Chang et al., 2015). Additionally, lack of trust can also be an issue, as online users can distrust online sales agents because they do not have the possibility to directly interact with these people, nor with the products that they are interested in. Some users experience a fear-based feeling when buying a product without directly touching it (Zaman, Anadarajan & Dai, 2010, p.295), looking for cues that allow them to get a proper understanding of the physical characteristics of the products.

Online buying behaviors and online social networks

Thanuskodi (2015) states that the need to be informed determines individuals to develop a process through which they identify the necessary information, which includes seeking, evaluating, selecting and using the information they need, and it can be referred as *information seeking behavior*. This process includes other behaviors which can be either intentional or passive, such as the occasional search or accidental encounter with a piece of information (Case, 2002). Ikoja-Odongo and Ochalla (2004) describe information seeking as the process that requires the cognitive capacity of the individual, but also their knowledge and abilities. By posting product or service related questions on online social networks, for instance, it can be suggested that the user is actively seeking for information (advice, opinions, details etc.), while combining this information with what was previously stored cognitively, from other sources and types of interaction with the online shop or other shops or online experiences.

The way in which users decide to get informed on online social networks related to the products or services they intend to acquire from online shops can be influenced by various factors, like what other users posted about products they bought (Kannan & Li, 2017). eWOM or electronic word-of-mouth “encompasses customers’ knowledge about the products, their usage, experience, recommendations, and complaints, and is generally perceived as trustworthy and reliable” (p. 27) and more effective compared to traditional marketing tools (Rauniar et al., 2014).

Jedrzej and López Locés (2017) found that most people tend to discredit sellers that have negative reviews even if these reviews are fewer than the positive ones, suggesting that a bad opinion has more weight than a positive one (p. 126). Considering the fact that users who buy online generally tend to perceive the behavior as being riskier, trustworthiness becomes the factor that can influence their decision making positively. Pappas (2016) identified three main risks that can influence decision making in the buying process: (1) the inability to examine whether the product will satisfy their needs before receiving it, (2) the post-selling services, (3) the inability to fully understand the system and the language that is being used in electronic sales. These sort of perceptions can lead potential e-shoppers to ask for advice on online social networks, so they can evaluate how other existing buyers or other users perceive the desired product or online service.

Trust represents an important factor associated with the development of the interest in using online stores in the buying process. The tendency to trust is seen as a personality characteristic leading to generalized expectations referring to the trust of others. Mayer, Davis and Schoorman (1995) suggested that trust is “the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party” (p.712). On the other hand, propensity to trust or the generalized tendency to trust others represents a stable factor within the group, affecting the probability that the group is trustworthy. For determining whether something is trustworthy or not, consumers look for indicators for trust and the effect of propensity to trust is to raise or reduce the signals of these indicators. Arora and Rahul (2017) demonstrated that consumer attitudes toward online shopping are significantly impacted by trust, which is a product of perceived web quality, website reputation and electronic word-of-mouth (p.373).

As far as information searching is concerned, studies demonstrated that there are positive relationships between the perceived benefits of social media information searching and the initial usage of this space for obtaining information (Mahrous, 2016). But on social media, users get involved in communities, and community belonging becomes essential as people get more and more engaged in distributed and inter-organizational groups (Fayard & Metiu, 2013), allowing individuals to identify with other community members and start thinking about “we” instead of “I” or “them” (Fayard & DeSanctis, 2010). This can be another factor that could influence the way users choose to advise their community when considering buying a product or service.

Methodology

The objectives of this research paper were to identify the users’ attitudes towards using Facebook as a means for information in the online buying process and to identify the factors influencing the use of Facebook for this purpose. The online social network Facebook was selected as this is one of the most frequently used social media platform in Romania. For the purposes of this research, a quantitative method was used, the survey. For data collection, an online questionnaire was used, which was applied in 2017. The questionnaire was distributed via Google forms platform and shared through Facebook.

The sample consisted of 166 students from the College of Communication and Public Relations, NUSPA, from Bucharest, Romania. The respondents, aged between 18 to 24, answered the invitation to respond to the online questionnaire after the invitation was posted on an online group on Facebook. The students are undergraduate (67%), master’s graduates (22%) and Ph.D. graduates (1%). 69% are females, while 31% are males; the majority of the participants live in the urban area (90%), while 9% live in the rural area. The questionnaires were completed online and the anonymity to this completion was guaranteed.

Scales of measurement

For measuring *we-ness*, referring to the affiliation of members to the community, we used a 3 items scale asking students whether they think of Facebook friends as “we” instead of “them”, how much friends on Facebook mean to them and whether they

identify with the community. In order to measure *propensity to trust*, a 3 items scale which included questions regarding the easiness to trust another person, the level of the tendency to trust and the disposition to trust without having information about the other party. *Online social network consulting* was For measuring *trust in internet shopping*, we used a 5 items scale which included questions regarding the attitude towards trusting online acquisitions, uncertainty perception, attitude towards online sellers and promise keeping, perception regarding others who shop online and on trusting the online stores they use. Community commitment was measured through a 3 items scale requesting participants to rate the degree to which they agree to the statements referring to their attachment to the Facebook community, to their emotional involvement and to their predisposition to enquire information from the community. For measuring these scales, students were asked to state their agreement level or value on 5 point Likert scales.

For measuring the internal validity of the proposed scales, Cronbach Alpha was applied; the results revealed high values in this sense: *consulting online social networks (Facebook)* $\alpha=0.952$, *trust in online shopping* $\alpha=0.802$, *community commitment* $\alpha=0.933$, *perception towards member affiliation (we-ness)* $\alpha=0.914$, *propensity to trust* $\alpha=0.900$.

Table 1. Descriptive statistics (means, SD, Cronbach Alpha) of factors that influence the decision-making process

No.	Item	Mean	SD	Cronbach's α
1.	Trust in online shopping	2.60	0.84	0.798
2.	Propensity to trust	2.34	1.04	0.900
3.	We-ness	2.71	1.29	0.914
4.	Community commitment	2.77	1.33	0.933
5.	Online social network consulting	2.01	1.26	0.952

Results

Firstly, the survey results showed that the students from our sample shop online a few times per year (42%) and once in every 2 or 3 months (23%), while only a less than a quarter are heavy shoppers, buying a few times per month (20%). Regarding their *information seeking behaviors*, our respondents use Facebook most of the times (22% very frequently, 20% on a frequent basis), while 15% confirmed that they do not use Facebook at all when they are researching for information for a new acquisition. Furthermore, most of the students agreed that online stores need a Facebook presence (more than 80%). As far as the page content they expect to see, the respondents mostly mentioned they agree that it should be less oriented towards sales (more than 70%).

Regarding *trust in online shopping*, the means ($M=2.6$, $SD=0.84$) showed that students are most trusting of online stores, specifically, more than 50% agree that a virtual store inspires them trust, while 22% agree that they are not trustworthy as they present plenty uncertainties. Also, more than 50% of the participants did not agree that online sellers are not able to keep their promise, while 23% is undecided, and over 23% considers this to be true to a high and very high degree. Regarding the trustworthiness

of the online stores where they buy products or, 64% agree with this statement to a high and very high extent.

As far as *community commitment* is concerned, 29% of the participants are emotionally attached to a very low degree and 23% to a low degree to their Facebook community, while 20% have a neutral standing point. Around 28% feel attached to their community members. On the other hand, members seem to represent an important source in obtaining the needed information when considering to buy something online, as 23%, respectively 21% go to Facebook for information, while 35% do this to a little extent or very rarely. This suggests that the Facebook community could be perceived as a valuable source of getting information by more than a third of the research sample, but there is also a consistent percentage not committing to this idea. The mean of this scale was $M=2.77$ $SD=1.33$, indicating a somewhat balance perception of community commitment within the sample that was studied.

By measuring *we-ness*, or member's affiliation to the community, the results showed approximatively similar values with the previous scale ($M=2.71$, $SD=1.29$). Almost a half of the respondents confirmed that the Facebook friendship does not mean a lot to them, 25 % being undecided, and around 30% confessing to this attachment. However, most of the respondents do not agree with the statement that they think of their Facebook friends as "we" instead of "they" (61%), while 16 % consider this to be true for them. 42% of our sample agreed that they do not identify themselves in the Facebook community which helps them trust in buying a specific product or service online, while 38% confirm this attitude.

The *propensity to trust* scale was developed for measuring the general tendency towards trust of the respondents. The values were rather inclined to a low degree ($M=2.34$, $SD=1.04$). Only 19% agreed that they can easily trust another person, 22% remaining undecided, and almost 60% did not agree with this statement. The second item asked the participants to rate the extent to which they agree that their tendency to trust another person is high, most of the participants (51%) shared that they did not agree to this to a low and very low extent. 26%, however, believe this to be true for them. As far as trusting other individuals that they do not know, the majority (76%) admitted not having this attitude. Thus, the results showed a low level of general trust for our sample.

Online social network consulting was measured by asking the study participants whether they post questions or advice about the products or services they buy online. In this sense, the mean value indicates that students barely participate in this type of behavior ($M=2.01$, $SD=1.26$). 46% of the respondents mentioned they never post questions on Facebook in order to obtain information about a product or service they intend to buy, while 30% rarely do this, and only 9,1% proceed with this for getting advice. Moreover, less than 17% post advice after buying a product or service from an online store, with 52% of the respondents never engaging in this sort of behavior, and 23% rarely doing so. These results prove a low contribution with valuable information for the community.

Regarding the factors influencing the acquisition process, 50% of the students reported that they are influenced by comments on the Facebook pages of online stores, while 28% are influenced by this to a low degree. Negative comments posted on Facebook photos of the products influence 46% of our sample, while 23% report not being influenced by this, and 18% are undecided whether this is important to them or not. Over 62% of the

respondents, however, are more inclined to buy a product if they find photos and information on Facebook about it, and 19% are influenced by this to a low degree. Responsiveness seems to be important according to our results: over 60% believe that their level of trustworthiness increases when the Facebook admin page answers all the questions that are asked on the page.

Considering the normal distribution of the tested variables, a Spearman correlation test was applied in order to identify whether there are statistically relevant relationships between the variables that were presented. The analysis showed a positive relationship between *we-ness* and *online social network consulting* ($r_s = .693, p < .01$), showing that the extent to which students perceive themselves as part of the Facebook community increases, the behavior of posting advice or questions regarding online stores also increases. The same positive relationship was identified when considering *community attachment* ($r_s = .646, p < .01$), indicating that once the attachment to the community increases, users tend to engage in informative behaviors on the community.

As far as *information seeking* on Facebook is concerned, the analysis reported a positive relationship with *trust in online shopping* ($r_s = .274, p < .01$), with *we-ness* ($r_s = .541, p < .01$) and *community commitment* ($r_s = .581, p < .01$), suggesting the possibility that users who are trusting the online environment for buying products or services are also using Facebook as a channel for obtaining information about what they intend to buy, and that this behavior increases with the feeling of belonging and attachment to the community. There is no significant relationship, however, between *information seeking* and the *propensity to trust*. But the *propensity to trust* and *trust in online shopping* both have a positive association with *online social network consulting* ($r_s = .163, p < .05$, and $r_s = .381, p < .01$).

The *frequency of online shopping* increases with *trust in online shopping* ($r_s = .447, p < .01$), with *community attachment* ($r_s = .335, p < .01$), and with *we-ness* ($r_s = .424, p < .01$), putting forward for consideration that the frequency of buying online is related to the favorable perception of the Facebook community and with the increase of trustworthiness of the online stores.

Table 2. Relationship testing between variables

Correlations	P value	R square
<i>We-ness -> online social network consulting</i>	**	0.693
<i>Community attachment -> online social network consulting</i>	**	0.646
<i>Trust in online shopping -> information seeking on Facebook</i>	**	0.274
<i>We-ness -> information seeking on Facebook</i>	**	0.541
<i>Community commitment -> information seeking on Facebook</i>	**	0.581
<i>Propensity to trust -> online social network consulting</i>	*	0.163
<i>Trust in online shopping -> online social network consulting</i>	**	0.381
<i>Trust in online shopping -> frequency of online shopping</i>	**	0.447
<i>Community attachment -> frequency of online shopping</i>	**	0.335
<i>We-ness -> frequency of online shopping</i>	**	0.424

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

Discussion

Firstly, the research results proved that a business presence on online social networks is relevant for a number of reasons, as young segments (between 18 to 24) mostly search on Facebook when considering to buy a product or service online, and also believe that online stores should have a business page to be consulted on this online channel. Users appreciate the involvement of the page admin in the comments that are posted on the page also take into account the comments and the impressions, especially the negative ones when they form an opinion about what they intend to buy. Previous research (Jedrzej & López Loces, 2017) showed that negative opinions or comments can impact a large number of people, even if the number of the negative reviews represents a minority, so it is important for online shops to respond to inquiries, with suggestions, recommendations, even to the negative mentions that are posted by clients, because it offers the business' perspective.

The role of trust and its importance in the buying decision process was emphasized before by other researchers (Tuteja et al., 2016; Martin et al., 2011). In our study, it is important to note that the attitude of trusting online shopping is connected to the information-seeking behavior on social networks and to the activity of posting questions and advice related to the acquisitions on the social networks. Online stores should monitor the way their targets get informed and identify the specific questions they ask referring to products or e-shops services. Moreover, the level of community attachment and affiliation are both linked to advising and asking for feedback on online social networks, so this could potentially mean that the users will attribute more value to what their members will be suggesting and to the information or opinion they are offering.

Generally, the participants mostly trust online stores and, particularly, the e-shops they do some research on. However, there is a significant percentage of the study participants who are either undecided or distrusting of online sellers, which could be a potential indicator of bad reputation or some negative claims they interacted with, which were proven to weight more compared to positive word-of-mouth.

In terms of content generation, our study results are similar to others (Romero et al., 2011; Ertiö et al., 2018) that confirm that social media users are rather passive consumers of content, and not engaging in contributing to the network. Very few students of our sample post questions or advice referring to the products or services they bought or intend to buy online, demonstrating their lack of actual involvement in the community.

As far as the third research question is concerned, the data analysis showed that there was no significant relationship between seeking information on online social networks and the general tendency of users to trust, which could suggest that the behavior of resorting to the online community for advice or pre-purchase information could be happening irrespective of the disposition to trust other individuals.

Limitations of the research

The study had a couple of limitations. Firstly, the data was collected online, which could interfere with the quality of the information that was obtained. Furthermore, the quantitative method of research allowed us to evaluate only one perspective of the

online shopping experience and some of the perceptions of the factors that influence the decision-making process and the information seeking experience in the pre-purchase stage of the buying process. More in-depth research is required for advancing the relevance of social media influence, the antecedents and the consequences of the consumer purchase intention in e-commerce. Additionally, the research investigated only the attitudes and opinions about aspects referring to the Facebook community and the functionalities it allows business owners to use for promotion, but the complexities behind the social media marketing efforts are much wider and they also need to be taken into account when evaluating decision making of users who intend to shop online.

Conclusions

Considering the wide variety of digital marketing and social media technologies that allow e-commerce businesses to promote their products or services and build and maintain relationships with publics, there is more need and interest in understanding the most effective ways in using these technologies for business benefits. Social media, in particular, represents a relevant source of information for users in the online purchase experience. Considering social media's interactive nature and the large volumes of user-generated content that it generates, it is especially important for e-shops to monitor and be actively present in this space, facilitating dialogue with interested publics and contributing with attractive content for potential prospects. As the online community can influence the perceptions of publics based on the information it provides, online businesses should invest time in understanding the digital micro-universes the users experience throughout their online journeys, getting more involved in implementing social networking functionalities on their buying platforms.

Abstract. *The foundation of building the excellence in the organization is the knowledge creation and its diffusion process. Knowledge is, in fact, a kind of "lever" of an organization's development and a source of its widely understood potential. An organization's excellence grows from the knowledge management processes and can be a challenge for managers to satisfy stakeholders. To create excellence in the organization is to follow some key concepts: results orientation, customer focus, leadership and constancy of purpose, management by processes and facts, people development and involvement, continuous learning, innovation and improvement, partnership development, corporate social responsibility. Many contemporary organizations try to find many potential solutions on the market to create good relations with stakeholders. The very important factor in the process of creation the excellence between the enterprise and its stakeholders is the effective way of communication. This is a theoretical and empirical article and its objective is to place the communication process in the contemporary innovative enterprise, as well as specify the role and importance of organization's excellence in the development of good relations with stakeholders. The article tries to answer to, among many others, the following questions: (1) What are the elements of the organization' excellence model? (2) How to build the communication process with stakeholders in the contemporary innovative enterprise? (3) What are the means of the communication in the process of building relationship with stakeholders? The research is based on own research made with top and middle managers in the innovative contemporary enterprises form Poland (listed on the NewConnect market).*

Keywords: *organization; excellence; communication; NewConnect; stakeholder.*

Introduction

Nowadays, the global world systematically "obliterates" geographic and demographic boundaries, because the information and communication technologies (ICTs) has created a new model of inter-organizational communication. The new balance of forces radically creates various relationships that "vertically" transform into "horizontal" relations, integrating various entities on the principles of "equality" and cooperation (including social ties). Contacts between various interest groups (stakeholders) affect many aspects of their business, e.g. economic activity. Despite the fact that today's enterprises focus in most cases on reducing operating costs, they must be reliable to

their nearest stakeholders, that is investors, customers or suppliers. Spontaneous contacts, for example in the form of mailing, telephone conversations or helpline, are the basis of modern communication of enterprises with its stakeholders.

The use of modern information and communication technologies, including the Internet, allows enterprises to design effective advertising campaigns or to improve supply and distribution channels. It is a derivative of the fact that these technologies allow, among others, for interactive and two-way communication between key stakeholders and the organization, for example in the form of asking questions or direct contact with a consultant, as well as creating knowledge (see: Janasz & Janasz, 2018). Striving for excellence, modern enterprises are outdoing themselves in their accessibility to clients, investors, suppliers, etc. – at the communication level, at the company-stakeholder level. This is mainly aimed at creating a competitive advantage and increasing the value of the company in the opinion of different classes of stakeholders (see: Gapinski, 2016; Beyer, 2018; Ziółkowska & Karbownik, 2018; Jabłoński, 2018; Grewiński, 2018).

The objective of the article is to place the communication process in the contemporary innovative enterprise, as well as specify the role and importance of organization's excellence in the development of good relations with stakeholders. The research is based on own research (using the CASI and IDI research methods) made with managers in enterprises listed on the NewConnect market in Poland. The paper consists of the two leading parts referring to the issues as follows: (1) theoretical part – the organizational excellence and building relationship by contemporary enterprises, as well as the main attributes of enterprises listed on the NewConnect market, and (2) empirical part – specification of the communication means used by enterprises in conducting the relationships with stakeholders.

Organizational excellence and building relationship with stakeholders

The concept of "excellence" from the management perspective can be considered in two ways – absolute and relative. In the case of the first approach, i.e. the absolute approach, one can describe the organization in a perfect condition, completely fulfilled on the market, which has no limitations. Of course, achieving such a state in the long run is simply impossible, and the pursuit of such a state may lead to the danger of activity due to the turbulent environment and the emergence of the risk of the organization itself. On the other hand, the relative approach of the organization's perfection describes not so much the state in which it should be found, but the situation in which the given entity is located, which is a kind of benchmark. This approach is related to building a competitive advantage and is a condition that can be achieved in the long run (Cyfert, 2013, pp.29-30). In reference to the organization's approach in the aspect of relativity, many theoreticians and practitioners of management created many business models defining the principles of excellence in organizations, based on the examples taken from the modern world of business. The principles of the organizational excellence model are presented below (Table 1).

Table 1. Principles of organization excellence model
(Farrar, 2004, pp.24-25; Steckel & Lehman, 1997; Yang, 2009, pp.931-943; Grunig & Grunig, 1998, pp.141-159)

Criterion	Explanation
Results orientation and mission fulfilment	Excellence is achieving results that delight all the organizations' stakeholders; employees are cultivated to achieve their maximum potential and recognize organization's stakeholders' needs.
Customer focus	Excellence is creating sustainable value and professional customer care before, during and after purchase.
Leadership and constancy of purpose	Excellence is visionary and inspirational leadership coupled with constancy of purpose (it must be a unique purpose for the each employee); constructive self-criticism is practiced and encouraged.
Management by processes and facts	Excellence is managing through a set of interdependent systems, processes and facts; doing the right thing is standard in the organization.
People development and involvement	Excellence is maximizing the contribution of employees through their development; there is a focus on staff training, besides employees matter in the organization and their needs are a high priority and they are promoted by management.
Continuous learning, innovation and improvement of intelligence	Excellence is using learning to create innovation and improvement opportunities; the organization easily "jump on" the technology and intelligence advanced levels to celebrate successes on the market.
Partnership development	Excellence is developing and maintaining value-added partnerships; the organization creates innovative strategies of cooperation for income generation and further development.
Corporate social responsibility	Excellence is exceeding the minimum regulatory requirements in which organization operates; organization takes care of different groups of employees and pays attention to ecological system of production and used resources.
Developed communication process	Excellence is using communication techniques to support processes within the organization and outside – with its stakeholders.
Continuous improvement of quality	Excellence is incorporating the critical success factors of TQM through quality control and assurance, quality information system, corporate culture committed to quality, quality objectives and strategy, etc.

Based on international literature Figure 1 shows model created by W. Wereda and J. Woźniak showing the main steps of process from learning organization to the intelligent one (more details in: Wereda & Woźniak, 2015, p.65, see also: Brzeziński, 2018). This model also highlights the differences between intelligent and learning and agile organizations, while pointing out that the basic model is the learning one – this framework introduces the basic mechanisms for creating and diffusing knowledge within the organization and between the organization and its external stakeholders. Knowledge management along with investing in human factor and initiating innovative processes in the organization are the foundations of building an agile organization model that stands out from the learning organization through increased operational flexibility (not only operational but strategic), high adaptability to changes in the environment, development of an early warning system, and blurring of organizational boundaries and virtualization of management processes. It is also important that risk management mechanisms are taken into account in the agile organization model. The very important factor in achieving by the organization level of excellence is the relative

approach and increase in intensity of bilateral communication and two-way relations with stakeholders (Fig. 1).

Figure 1. Basic steps of creating organization excellence model through building relationships with stakeholders (based on: Wereda & Woźniak, 2015, p.65)

According to many studies there are presented different aspects of successful stakeholder relationship management (SRM) in various types of organizations. Therefore, achieving success in managing stakeholder relationships is long-lasting and can be reached only by a long-term commitment to a structured process, which is focused on: identifying stakeholders, understanding their expectations, managing those expectations, monitoring the effectiveness of stakeholder engagement activities, as well as continuous review of the stakeholder community (Bourne, 2009, p.4). The whole process must be supported by clear and effective way of communication because both sides must respect mutual goals and accept risk possibilities during value creation delivering. Stakeholders in the contemporary turbulent time look for trust and rely on strong network communication in developing cooperation with any organization or individuals (Wereda et al., 2016, p.38).

Methodology of the research

The empirical study was carried out in three main stages. The first of these was a survey (using the CASI method) on a sample of 60 innovative companies listed on the NewConnect market in Warsaw. The second stage was to conduct 11 in-depth interviews among respondents previously included in the CASI study. The IDI research was aimed primarily at understanding the specific nature of the issues raised in the CASI study, with particular emphasis on respondents' opinions on the scale and scope of use of specific communication tools with different classes of stakeholders, as well as identification of motives for using or not using of specific communication tools in continuous development company. Quantitative research (CASI) has been supplemented with a qualitative study. In addition, the IDI survey's results were to additionally verify the observed trends demonstrated in the CASI study in the use of specific communication tools with stakeholders. An analysis of the market situation (value of shares) of 11 respondents (in the form of IDI) of enterprises was also made and they were referred to general trends in the use of modern or traditional communication tools with stakeholders – it was the third stage of the research.

Thus, the study used a triangulation method (see Mathison, 1988; Flick, 2004; McFee, 2006; Annells, 2006; Carter et al., 2014) on three levels specified by N. Denzin (2006): data triangulation – comparison of research carried out at different time intervals, triangulation of researchers – conducting research by various researchers, as well as

triangulation of methods – combining a variety of research methods (see Jick, 1979; Olsen, 2004).

The basic components of the survey methodology are presented in Table 2.

Table 2. Methodology of the research (own study)

The components of methodology	Specification
Research scope	The means of conducting the communication processes with stakeholders by the NewConnect companies.
Research objective	Identification of basic means used by NewConnect companies in the communication processes with stakeholders, as well as specification of the role and importance of those means in the organization's excellence development (in the framework of developing good relations with stakeholders).
Research tools	Computer Assisted Self-Interviewing (CASI), Individual In-Depth Interview (IDI), as well as market data/shares' value analysis.
Entity carrying out the study (CASI research)	Centre of Marketing Research INDICATOR Limited Liability Company with its registered office in Warsaw, ul. Świętojerska 5/7, 00-236 Warszawa.
Entity carrying out the study (IDI research)	Research Institute IPC Limited Liability Company with its registered office in Wrocław, ul. Ostrowskiego 9, 53-238 Wrocław.
Entity carrying out the study (market data analysis)	Workers of the Institute of Organization and Management (Military University of Technology in Warsaw): Jacek Woźniak, M.A., as well as Wioletta Wereda, Ph.D.
Period of study (CASI research)	2 months (November – December 2016).
Period of study (IDI research and market data analysis)	2 months (March – April 2018).
Scope of study (CASI and IDI researches)	The whole Poland (16 voivodships).
Respondents	Managers or managers responsible for IT, environment or innovation, employed in NewConnect-listed companies (1 respondent per business).
Criteria for selection of research sample (CASI research)	Systematic random sampling (including the criterion of the leading business profile indicated for the purposes of the NewConnect market record) in layers (layers correspond to enterprise size).
Criteria for selection of research sample (IDI research)	Enterprises chosen from the CASI research sample – the main criterion of choosing was the number of enterprises surveyed in CASI research according to the criterion of leading business profile. In the IDI research the chosen groups were: trade, computer sciences, manufacturing, financial services, advice and training, building & construction.
Groups of stakeholders in the survey (CASI and IDI researches)	4 groups: internal stakeholders, institutional clients, individual clients, as well as other entities, e.g. external processes' subcontractors, intermediaries, shareholders.
The size of the research sample (CASI research)	N = 60 enterprises (28% of the population – the population constituted of 214 companies, i.e. SMEs and large enterprises

The components of methodology	Specification
	from the NewConnect market, which are based in Poland and mainly operate in Poland).
The size of the research sample (IDI research and market data analysis)	N = 11 enterprises (chosen from the CASI research sample).
Structure of the questionnaire (CASI research)	The questionnaire included: 4 questions answered using a 5-point Likert scale) – each question dedicated to the specific group of stakeholders.
Structure of the questionnaire (IDI research)	The questionnaire included: 11 opened questions.

Among all 60 companies (CASI survey), 11 entities dealt with trade, 30 entities provided various types of services, while 19 enterprises operated in the industry or industrial processing. The research sample was dominated by small enterprises (10-49 employees) – there were 37. A little less were medium-sized or large enterprises – 23 entities. In terms of the age criterion, the "old" companies were dominant in the study, i.e. 25 entities were operating on the market over 15 years. The smallest group were "young" enterprises, i.e. operating on the market for less than 10 years – there were 16 in the sample. In addition, all surveyed enterprises operated on a regional and national scale – 60 entities, while only 25 entities operated on a European scale, and only 5 on the international scale (Woźniak, 2018) (Table 3).

Table 3. Specification of the research sample – CASI research (own study; N=60)

The basic criteria of the research sample's specification	The size of the enterprise		In general (number of enterprises)
	Small (10 – 49 employees)	Medium and large (≥50 employees)	
Leading business profile – NewConnect classification			
Trade	7	4	11
Services (computer science, advice and training, financial services, eco-energy, recycling, media)	21	9	30
Manufacturing/ industrial processing	9	10	19
In general	37	23	60
The age of the enterprise			
Less than 10 years	13	3	16
10 – 15 years	11	8	19
More than 15 years	13	12	25
In general	37	23	60
The scale of the business (multiple choice question)			
Local (1 city/municipality/district)	35	23	58
Regional (1-8 voivodships in Poland)	37	23	60
National/domestic (9-16 voivodships in Poland)	37	23	60
European (at least 1 country in Europe outside Poland)	14	11	25

The basic criteria of the research sample's specification	The size of the enterprise		In general (number of enterprises)
	Small (10 - 49 employees)	Medium and large (≥50 employees)	
International (at least 1 country in the world outside Europe, including outside Poland)	3	2	5

The IDI study included 2 enterprises conducting commercial activity, 5 enterprises providing services and 4 companies involved in industrial processing (Table 4). It is worth noting that the quantitative structure of enterprises in terms of the criterion of the leading business profile in the IDI study reflects the proportions of the quantitative structure of enterprises in terms of the same criterion for the CASI study (Table 3).

Table 4. Specification of the research sample - IDI research (own study; N=11)

Leading business profile (NewConnect classification)			In general (number of enterprises)
1.	Trade		2
2.	Services	Computer science	2
		Financial services	2
		Advice and training	1
3.	Manufacturing/industrial processing	Manufacturing	2
		Building & construction	2
In general			11

At this point it should be noted that the conducted study is treated as a pilot study, and the obtained results are only an indication of the direction for further research in the selected area and attention to the basic mechanisms of operation of the surveyed enterprises in the use of specific communication methods (to achieve the so-called excellence organization in shaping relations with stakeholders).

Innovative enterprises on the NewConnect market - the main attributes

The NewConnect market is an alternative market (i.e. Over The Counter - OTC) organized by the Warsaw Stock Exchange. Generally, it can be assumed that securities and money market instruments are traded on the OTC markets. Alternative markets offer investors the opportunity to allocate capital in innovative industries, and companies listed on these markets offer investors a high return on investment, while at the same time increasing the risk of investment (NewConnect, 2015; Woźniak & Wereda, 2018, p.418).

The NewConnect market was launched on August 30, 2007. It was created mainly for small and medium-sized enterprises with high growth potential. The main purpose of launching this market was to enable the development of teams that faced difficulties in obtaining financing for development (NewConnect, 2015, p.15). The NewConnect market offers cheaper capital acquisition, which companies use to implement the assumed development strategy. For many companies, this market is the beginning of the way to the Main Market of the WSE (NewConnect, 2015, p.15).

Companies listed on the NewConnect market are characterized mainly by (NewConnect, 2015, pp.9 et seq.; Woźniak & Wereda, 2018, p.419): (1) small or medium size; these are mainly new entities (start-ups) or enterprises in the early stages of development, looking for ways to build value on the market; (2) high growth potential and flexibility; (3) running business in innovative sectors and branches, including ecology, specialist services, advanced technologies and financial services; (4) the desire to quickly raise capital for development, including for improvement of specific production processes (know-how) and activities related to, among others with establishing business relations (B2B), clients (B2C) and with state and local administration entities (B2A); (5) difficulties in obtaining financing, resulting, inter alia, from the low level of development of the markets on which these enterprises operate, the low level of social trust in this type of activity, or the high cost of capital offered by banks.

Attributes of companies listed on the NewConnect market may suggest a high level of risk in operations – mainly operating. The level of operational risk in these entities is also influenced by the broadly understood environment - both internal and external. Limiting the "negative" as well as stimulating "positive" risk is associated with shaping relationships with various groups of stakeholders, both employees of companies, shareholders, clients, administration, etc. It is all the more important because it is generally assumed that the very nature of business operations from the NewConnect market requires entering into interaction with external stakeholders, e.g. in the area of acquiring resources, improving the flow of information, or establishing new and lasting relationships – to gradually reduce the level of uncertainty and risk in the environment, and to build the company's market value and provide the basis for further external financing by shareholders (Woźniak & Wereda, 2018, pp.418-419; Woźniak, 2018).

The pursuit of enterprises from the NewConnect market to organizational excellence – through shaping relations with stakeholders – is currently associated with the use of certain modern ways of communication (ICTs). Thanks to this, these companies can, among others (based on: Woźniak, 2018): (1) support planning and forecasting processes; (2) improve innovation activity, e.g. by supporting processes of knowledge creation and diffusion; (3) enter network structures (also virtual), e.g. in the form of industry clusters, thanks to which they may have access to rare resources of key importance for their development; (4) improve the efficiency of supply, production, promotion and distribution channels of products and services (including innovations); (5) increase the scale and scope of activity – thanks to ICTs, companies from the NewConnect market can operate globally – the criterion of geographical location of operations is not a limitation for their development.

At this point, however, it should be noted that communication with stakeholders not only with the use of ICTs can be the basis for the companies' striving for the so-called organizational excellence. Noteworthy are also traditional forms of communication, such as telephone conversations or traditional letter correspondence or the circulation of paper documentation. In the further part of the study, the results of the empirical study will be presented, showing which ways of communication with different classes of stakeholders are most often used by enterprises from the NewConnect market.

Innovative enterprises and their communication with stakeholders – results of the research and discussions

The empirical study (CASI) lists four basic classes of stakeholders, in shaping relations with which companies from the NewConnect market use specific communication methods (traditional and modern). These classes are: (1) internal stakeholders, (2) institutional clients, (3) individual clients, as well as (4) other entities, e.g. external processes' subcontractors, intermediaries, shareholders. In the case of the above-mentioned groups of stakeholders, 11 basic methods of communication were taken into account (Table 5).

On average, the surveyed enterprises use the following communication methods/tools in communication with internal stakeholders: (1) e-mail accounts – the average value of answers in a 5-point scale is 4.93, (2) traditional phone calls – the average value of answers is 4.48, (3) direct talks and meetings – the average value of answers is 4.43, as well as (4) paper documentation – the average value of answers is 4.40. In addition, in the case of the above methods/tools of communication with internal stakeholders, a relatively strong negative skewness of the response distribution can be observed, which indicates that the majority of respondents' answers are above average values for the frequency of use of particular communication methods – and thus confirms that in the opinion of the respondents, the four ways of communication indicated above are the most important in building relationships with employees and may potentially have the greatest impact on the improvement of the organization "from the inside" (Table 6).

Table 5. Basic means in communication with stakeholders used in CASI research (own study)

No.	Basic means of communication with stakeholders
1.	Traditional way of communication – in the form of paper documentation.
2.	Traditional way of communication – in the form of direct conversations (face to face) and team meetings.
3.	Telephone communication (i.e. traditional phone calls).
4.	Communication with the use of e-mail accounts.
5.	Communication with the use of traditional forms of promotion (advertising in the press, TV, radio, PR, sponsorship).
6.	Communication with the use of intranet (e.g. exchange of electronic documents, execution of orders, development of schedules with tasks, etc.).
7.	Communication with the use of enterprise's/corporate's portals (personalized user accounts).
8.	Communication with the use of teleconferences.
9.	Communication with the use of external messengers, e.g. Gadu-Gadu, GTalk, Hangout, Skype, etc.
10.	Communication with the use of external memory cases, e.g. for storing and sharing documents.
11.	Communication with the use of social networks, e.g. Facebook, Google+, LinkedIn, Twitter, etc.

In the case of shaping relations with external stakeholders – and more specifically institutional clients – the situation is similar. It is connected with the fact that the

surveyed enterprises most often use the following communication methods in communication with this class of stakeholders: (1) e-mail accounts – the average value of answers in a 5-point scale is 4.85, (2) traditional phone calls – the average value of answers is 4.75, (3) paper documentation – the average value of answers is 4.57, and (4) direct talks and meetings – the average value of answers is 4.30. In the case of the above-mentioned methods of communication with institutional clients, a strong negative skewness of the response distribution can be observed, which indicates that the vast majority of respondents' answers are above the average values for the frequency of individual communication methods – thus confirms that in the opinion of the respondents indicated above four communication methods are key in building relationships with institutional clients (Table 6).

Table 6. Leading means in communication with stakeholders used by the surveyed enterprises listed on the NewConnect market – CASI research (own study; N=60)

Leading means in communication	Average	Standard deviation	Skew	Coefficient of variation
Internal stakeholders				
Paper documentation	4.40	0.827	-1.619	18.80%
Direct conversations and team meetings	4.43	0.789	-1.165	17.81%
Telephone (traditional phone calls)	4.48	0.833	-1.854	18.59%
E-mail accounts	4.93	0.312	-5.114	6.33%
External stakeholders – institutional clients				
Paper documentation	4.57	0.945	-2.626	20.68%
Direct conversations and team meetings	4.30	0.997	-1.282	23.19%
Telephone (traditional phone calls)	4.75	0.728	-3.667	15.33%
E-mail accounts	4.85	0.685	-4.719	14.12%
External stakeholders – individual clients				
Direct conversations and team meetings	2.95	1.478	-0.302	50.10%
Telephone (traditional phone calls)	2.43	1.854	0.555	76.30%
E-mail accounts	2.52	1.944	0.504	77.14%
External stakeholders – other entities, e.g. external processes' subcontractors, intermediaries, shareholders				
Telephone (traditional phone calls)	4.80	0.443	-2.124	9.23%
E-mail accounts	4.83	0.615	-4.860	12.73%

However, in the case of shaping relationships with individual clients, the situation is slightly different. Despite the fact that the same means of communication prevail in the respondents' answers, the average values are much lower than for the two above-described classes of stakeholders. On average, the surveyed enterprises most often use the following communication methods in communication with this class of stakeholders: (1) direct talks and meetings – the average value of answers on a 5-point scale is 2.95, (2) e-mail accounts – the average value of answers is 2.52, as well as (3) traditional telephone calls – the average value of the answer is 2.43. In addition, in the case of the above-mentioned methods of communication with individual clients, either a weak negative or a weak positive skewness of the response distribution can be observed,

indicating that: (1) the slightest majority of responses are above average values, or (2) the slightest majority of responses respondents are below the average values for the frequency of use of particular communication methods. This means that it cannot be unambiguously assumed that the three ways of communicating with individual clients indicated above are crucial in building relationships with them. This is also confirmed by the high value of the coefficient of variation – which indicates that the respondents differed significantly in their assessment of the use of these communication methods. In the first two groups of stakeholders described, the coefficients of variation were at a much lower and acceptable level (Table 6).

On average, the surveyed enterprises use the most in communication with the so-called other classes of external stakeholders the following methods/communication tools: (1) e-mail accounts – the average value of responses on a 5-point scale is 4.83, and (2) traditional phone calls – the average value of answers is 4.80. In the case of the above-mentioned communication methods/tools, a strong negative skewness of the response distribution can be observed. Therefore, it is confirmed that in the opinion of the respondents, the two methods/communication tools indicated above are the most important in building relationships with this group of external stakeholders. Moreover, the coefficient of variation is relatively low, which indicates that the respondents did not differ significantly in their responses, i.e. in the assessment of the use of these communication methods (Table 6).

In the case of shaping relations with internal stakeholders, respondents most often declared (among the communication methods indicated in Table 5) that "very often" they use: e-mail accounts (95% of responses), traditional telephone calls (65%), direct conversations and meetings (60%) and paper documentation (57%). Respondents "often" use: paper documentation (30%), direct talks and meetings (22%) and traditional telephone calls (22%). On the other hand, respondents most often declared that they "sometimes" use: direct talks and meetings (22%), as well as traditional telephone calls and paper documentation (12% each). Answers "rarely" and "never" practically did not appear in the respondents' declarations for the indicated ways of communication with internal stakeholders (Fig. 2).

In the case of shaping relationships with institutional clients, respondents most often declared (among the modes of communication indicated in Table 5) that "very often" they use: e-mail accounts (95% of responses), traditional telephone calls (85%), paper documentation (75%), as well as face-to-face calls and meetings (60%). Respondents "often" use: paper documentation and direct talks as well as meetings (17% each) and traditional telephone calls (10%). However, respondents most often declared that they "sometimes" use direct talks and meetings (18%). Answers "rarely" and "never" appeared in the respondents' statements relatively rarely and did not exceed the 3% threshold for indicated ways of communicating with institutional clients (Fig. 3).

Figure 2. Means most commonly used by the surveyed enterprises in communication with internal stakeholders (own study; N=60)

Figure 3. Means most commonly used by the surveyed enterprises in communication with external stakeholders - institutional clients (own study; N=60)

In the case of shaping relationships with individual clients, respondents most often declared (from among the communication methods indicated in Table 5) that they "very often" use e-mail accounts (37% of responses) and traditional telephone calls (28%). Respondents "often" and "sometimes" use primarily direct conversations and meetings (respectively: 38% and 15%). For this class of external stakeholders, the answer "never" is the most exposed – such a declaration of respondents usually appears for email and

traditional telephone calls (62% each), as well as face-to-face calls and meetings (32%) (Fig. 4).

Figure 4. Means most commonly used by the surveyed enterprises in communication with external stakeholders – individual clients (own study; N=60)

In the case of forming relations with the so-called other classes of external stakeholders, respondents most often declared (among the methods of communication indicated in Table 5) that they "very often" use e-mail accounts (90% of answers) and traditional telephone calls (82%). Respondents "often" use primarily traditional telephone calls (17%). Answers "sometimes", "rarely" and "never" appeared in the respondents' statements relatively rarely and did not exceed the 2% threshold for indicated communication methods (Fig. 5).

Figure 5. Means most commonly used by the surveyed enterprises in communication with external stakeholders – other entities (own study; N=60)

Taking into account the results of the CATI survey, it can be noticed that the surveyed companies apply in principle the same methods of communication with different classes of stakeholders – which may be somewhat surprising and puzzling. In addition, respondents declare the use of mainly traditional means of communication, putting much less emphasis on modern/innovative solutions, which in a sense are characterized by a high level of technological advancement. In order to better understand the

specificity of this phenomenon, in-depth interviews (IDI) conducted on a sample of 11 entities that previously participated in the CATI survey will be analyzed.

Based on IDI interviews, it is generally possible that enterprises use simple and traditional means of communication mainly because they are cheap to implement and maintain, can be easily and quickly acquired, and they are widely used – so there will be no problems with their technological integration with solutions used by stakeholders. In addition, the methods/tools of communication with stakeholders used in many cases mainly serve to support operational management and the ongoing exchange of information resources. Therefore, modern/innovative and technologically advanced solutions are not required. In addition, the surveyed enterprises are characterized mainly by either small or medium size, so there is no need for a strong development of IT infrastructure in the area of communication with stakeholders – mainly internal ones. In many of the cases studied, communication with stakeholders does not support the processes of knowledge management and innovation processes. Respondents also do not treat communication with stakeholders as a basis for creating enterprise value – which to some extent suggests depreciation of communication in managing surveyed entities, especially that the basis of their functioning (external funding) is communication with stakeholders, e.g. clients or co-developers of innovative basic processes. Improving/modernizing methods/tools of communication with stakeholders is usually a cost for the surveyed enterprises than the source of development, e.g. in the long run (Table 7).

**Table 7. General approach to conduct communication with stakeholders
– IDI research (own study; N=11)**

No.*	Branch/sector	General approach (opinions of respondents)
E1.	Financial services	"We mainly use simple tools and try to incorporate communication into strategic activity, but this is not a priority. We do not strive for a strong expansion of the IT infrastructure. We do not see the basis for communication of innovative processes. What counts is mainly the support of short-term goals by data analysis and information exchange".
E2.	Manufacturing	"We use simple, traditional means of communication – mainly in operational activities. We do not see the creation of a competitive advantage in communication. We have a strongly developed information asymmetry in the company – each employee has access to specific information resources".
E3.	Trade	"In communication, we use simple, ordinary tools that are widely offered by major global suppliers. We also work on our own software, which we create and develop. We do not see the need to significantly expand the technical infrastructure for communication – we mainly use external solutions. Communication with stakeholders is not a key element in shaping the company's strategy".
E4.	Advice and training	"In dealing with stakeholders, mainly customers, we use both simple, traditional and advanced, modern ways/ communication tools. We are mainly interested in ongoing communication with clients and promoting the market. However, we do not treat communication with stakeholders as the basis for building a competitive advantage in the market, at least not in the full sense of the word".

No.*	Branch/sector	General approach (opinions of respondents)
E5.	Manufacturing	"Communication is carried out practically with all stakeholder groups. For us, communication is the key, but we do not think it is the source of creating a competitive advantage. Communication improves the ongoing implementation of processes. For us, contact with employees and customers, contractors is crucial. We generally use relatively simple ways/communication tools – both developed for our order and generally available".
E6.	Computer science	"We treat communication with stakeholders as a source of competitive advantage. We use both simple and advanced communication tools – standard available on the market. We are also able to develop communication tools for ourselves, but it is not always necessary. On a large scale, we develop communication between employees, and in the case of communication with external stakeholders, we do not see the need to go beyond "standard" solutions, such as e-mails, websites and telephone communication".
E7.	Building & construction	"We are open to new solutions and opportunities offered by the market in the field of communication, mainly with clients. For us, this is the basis of business operations. We use both simple and advanced ways of communication. Communication is a source of competitive advantage".
E8.	Building & construction	"Communication with employees and potential clients is important to us. We mainly use simple solutions. Communication is not crucial in creating the value of a company and in the implementation of innovative processes".
E9.	Computer science	"Communication is an important process for us and it mainly concerns the exchange of data and information between us and our partners and clients. We use both simple (mainly in communication with clients, co-operators and employees in current affairs) as well as advanced communication tools (in communication with employees – to analyze and transmit data in the implementation of basic processes). Communication is important to us in innovative processes".
E10.	Financial services	"In communicating with stakeholders, we mainly use simple tools that we support over the Internet, such as instant messengers and spreadsheets. We do not need advanced technologies/tools. Communication is not the basis for creating a competitive advantage for us".
E11.	Trade	"We use technologies that are currently on the top and are used by young people 24 hours a day. Although our company is large and has a huge reach, we use the simplest communication tools because they reach all key stakeholders. Communication can be a source of enterprise's value".

* The names of the surveyed companies cannot be given to the public information.

Despite the fact that the enterprises use mainly traditional means of communication, and the communication itself is perceived through the prism of operational management and does not see a great potential for creating enterprise value, it is worth noting that both the scale and the scope of communication are shaped mainly at medium or high level – both for internal and external stakeholders (Table 8). This is important because it points to the fact that in the surveyed enterprises (Table 8): (1) processes of full and ongoing communication are covered by the majority of identified stakeholders,

i.e. there are stakeholders in the minority with whom communication is sporadic, substantively limited or "neglected" at all; (2) communication with key stakeholders concerns mainly basic processes (creating value for internal and external stakeholders), or both basic and auxiliary processes – therefore the level of complexity and significance (for the enterprise) of communication with stakeholders is high; in a minority there are sssssenterprises in which communication with stakeholders supports only auxiliary processes.

**Table 8. Scale and scope of communication with stakeholders
– IDI research (own study; N=11)**

No.*	Scale** and scope*** of communication		Change in the market value****
	Internal stakeholders	External stakeholders	
E1.	Scale: medium; Scope: big	Scale: small; Scope: small	Small increase ↑
E2.	Scale: medium; Scope: medium	Scale: big; Scope: small	No change
E3.	Scale: big; Scope: medium	Scale: medium; Scope: medium	Small decrease ↓
E4.	Scale: big; Scope: big	Scale: medium; Scope: big	Small decrease ↓
E5.	Scale: big; Scope: big	Scale: big; Scope: big	Small increase ↑
E6.	Scale: big; Scope: big	Scale: medium; Scope: big	Big decrease ↓↓
E7.	Scale: medium; Scope: big	Scale: medium; Scope: medium	Big increase ↑↑
E8.	Scale: big; Scope: big	Scale: medium; Scope: big	Small decrease ↓
E9.	Scale: big; Scope: big	Scale: medium; Scope: big	Small decrease ↓
E10.	Scale: medium; Scope: big	Scale: medium; Scope: medium	No change
E11.	Scale: big; Scope: big	Scale: big; Scope: big	No change

* The same numbers of enterprises like in Table 7.

** The scale is treated as the number of different stakeholders, covered by the full and current communication. Levels – small: ≤30% identified stakeholders, medium: 30-60% identified stakeholders, big: ≥60% identified stakeholders.

*** The scope is treated as the level of complexity and significance (from the enterprise's point of view) of activities/processes covered by communication with stakeholders. Levels – small: mainly the supporting processes, medium: mainly the basic processes, big: both the supporting and basic processes.

**** Value of the enterprise – in the last 5 years.

Among the 11 surveyed enterprises (IDI survey) one can observe mainly a decrease or no change in their market value in the last 5 years (Table 8). This may suggest in a somewhat (obviously simplistic way) that not always simple and basic communication methods and tools are sufficient to be able to develop properly, i.e. sustainably and structured in the long run. It is also worth noting that the depreciation of communication with stakeholders (and in particular its "maturity" and technological advancement) in the processes of creating the value of the enterprise is a mistake. The same applies to the implementation of advanced and complex substantive (also multilateral, involving various entities) communication in innovative processes. The NewConnect market is demanding in terms of business activity of companies that want to obtain external financing should engage in greater expenditure on improving communication with

stakeholders. Of course, the market value of the surveyed companies does not depend only on the processes of communication with stakeholders, but may be of great importance here. Taking into account the fact that the surveyed enterprises (IDI study) usually consist of ongoing and full communication the majority of their stakeholders, as well as communication with them concern both the basic and auxiliary processes, it is necessary to consider why the market value of these enterprises or it does not change significantly or decreases (Table 8). One of the reasons may be the "neglect" of communication with stakeholders and the lack of investment in this respect. The surveyed enterprises in many cases declare that in the communication processes they are guided by the needs of stakeholders, but this does not have to be true. Respondents also do not indicate how they verify the level of fulfilment of these needs. The main criteria for selecting communication methods/tools are cost and time. This may not always be the usefulness of stakeholders. Many needs in the field of communication, which may have an impact on organizational innovation and knowledge management, may not be noticed by the owners/management at all.

Conclusions

Communication with stakeholders (internal and external) is an important element in the development of activities by modern enterprises in various industries and sectors. Without efficient communication, it is not possible to create new, useful knowledge and to act with it with cooperating entities. Lack of communication "closes" enterprises and deprives them of key resources. The pursuit of the so-called organizational excellence therefore requires extensive communication with stakeholders – going beyond the scope of only acquiring or providing data and information resources. A wider perspective on communication is needed, which should be a "tool" for joint creation of knowledge and mutual improvement of enterprises through permanent and complex business and social relations. This is due to from the fact that modern enterprises operate under the so-called knowledge-based economy (KBE).

In the surveyed enterprises from the NewConnect market (which are treated as innovative entities operating in modern and future industries), one can observe specific technological shortcomings and organizational "negligences" in the implementation of communication processes with different classes of stakeholders. In addition, communication processes are given little importance in the processes of creating knowledge and in the innovative activity of the surveyed enterprises. On the other hand, a relatively large scale and a large scope of communication can be noted in these entities. This is a situation that mainly indicates the lack of awareness of the owners/managers regarding the potential from the development of communication processes, e.g. through the use of modern and advanced ICTs, or the lack of technological and financial opportunities for the development of IT infrastructure. Another explanation for this situation is simply the lack of needs of the surveyed enterprises in the field of modernization of the portfolio of communication tools with stakeholders, especially those crucial from the point of view of creating a market advantage. It may, however, reflect on the decline in their market value in most of the surveyed enterprises in the long-term. It may be (but does not have to) the effect of, among others "negligence" in the improvement of communication processes with stakeholders.

In summary, communication processes can have an impact (at least partial and indirect) on the value of modern enterprises and the pace of their development by shaping

relationships with various classes of stakeholders that are necessary, among others to create a positive and strong synergy effect and create knowledge. Without efficient and modern communication, it is difficult to reach the so-called organizational excellence – even enterprises founded on innovative, operating in modern industries with high technological potential.

Abstract. *Organizations are focused to constantly change their communication strategy in order to be in trend with the social and technological development. The pressure to be up to date, innovative and presenting something new every time are engaging with their public is even bigger in online communication. This study takes a close look at organizational and social factors that influence online communication strategy in Romania. Qualitative analysis was conducted based on 10 communication briefs from 10 different brands whose daily activities are based in Romania. By coding relevant quotations from the documents analyzed we have identified which are the organizational factors and which are the social factors that influence online communication strategy of brands that are part of multinational corporations in Romania. New routes of development in practice have been identified as well as new areas for research.*

Keywords: *communication strategy; social factors; organizational factors; online channels; cultural influence; Romanian brands.*

Introduction

The public relations practice is growing rapidly around the world due to the technological changes. But this growth is uneven because public relations practice and education are concentrated in the United States and Western Europe (Botan, 1992, p.149) and are less advanced in the rest of the world. However, due to the rising of the internet, many major companies have now the possibility to conduct business in more than one country, including Romania, so they are called *multinational corporations* (MNC's). Therefore, MNC's are working with local public relations practitioners in order to achieve their business goals.

In the context of a more local communication, it is crucial for public relations practitioners to understand the most relevant factors in building the communication strategies. Therefore, this article takes a closer look to the factors that influence the communication strategy. First, a literature review will support the idea that there are two important types of factors that are influencing the communication strategy: social factors and organizational factors. On the basis of the factors mentioned in the literature review, a qualitative analysis study was conducted in order to explore 10 communication briefs belonging to 10 important Romanian brands with activity in areas such as food, beauty, telecom, health, gas and oil, financial, entertainment or software.

Analyzing the documents helped to identify the most relevant factors that are influencing the communication strategy in the Romanian market as well as new areas for research.

Literature review

Technological and social pressure force brands to constantly change the business strategy. In online communication, the pressure to react now, in a creative way, with a low budget and high results is even bigger. But even under the pressure of time, a good communication strategy begins with a good formulation of it (Allio, 2005). Coman considers that a strategy should be determined by the following organizational factors: financial resources, public, business objectives, context and qualities of the public relations practitioners (Coman, 2006, p. 98). Following this line, researchers have identified others organizational factors such as organizational structure, informational system, type of leadership, managers, budget or motivation (Pearce & Robinson, 2011).

It's important to note that this list of organizational factors is not exhaustive, on the contrary, it could include others factors as well depending on the communication purpose such as organizational culture, company dimension, regional or global influence, legal regulations, the type of activity, type of product, market or competition. This is the reason why, when it comes to communication strategy, researchers propose a *holistic theoretical model*. Okumus (2001) has organized the factors that could influence the communication strategy in four categories in order to present his holistic theory: (1) *content* – strategic decision, implementation; (2) *context* – it could be intern (organizational structure, organizational culture, organizational learning) and extern (environment and social behavior); (3) *process* – planning, resources, human resources, communication, monitoring, feedback and external partners; (4) *results*. But the *holistic model* presented by Okumus could be improved by including one more step between context and process and it should be the *communication channel*, which has the potential to influence how the message is transmitted to the public.

But research is more focused on organizational factors that are influencing the communication strategy and less on the social factors that could have an input in the public relations practices such as nature of culture, for example. When thinking about culture and public relations, the theoretical framework of Geert Hofstede (1997) comes to mind, which has been considered a good start for understanding the dynamics of intercultural and organizational communication and public relations. Hofstede identified five cultural variables that influence communication and relationships in organizational settings: power distance, uncertainty avoidance, masculinity/ femininity, individualism/ collectivism and Confucianism or long term orientation (Hofstede, Hofstede & Minkov, 2012).

Sriramesh and Verčič (2003) believe that it is important for public relations professionals to be able to predict the best way to practice public relations in a particular country or region (Sriramesh & Verčič, 2003). Both authors also support the idea of identifying the relationships between public relations and other environmental variables in order to increase the ability to predict which strategies and techniques are better suited to a particular organizational environment. In their theoretical framework based on anecdotal evidence, they described five interrelated factors that influence public relations practices: (1) *political system* – public relations practices depending on

the level of public opinion in each country; (2) *level of economic development* – closely linked with the political ideology because political conditions affect economic decision-making in every country and vice versa; (3) *level of activism* – is important for practitioners to establish the nature of activism and determine how it influences the public relations activities in that country; (4) *nature of culture* – communication influences and is influenced by culture; logically, culture affects public relations and public relations help alter culture; (5) *nature of media system* – media relations represent an important focus for a public relations practitioner in order to establish a positive relationship (Sriramesh & Verčič, 2013). These five environmental variables have the potential to identify the uniqueness of the context for public relations practice in each nation or culture, thereby also affecting the choice of public relations strategies and practices.

In intercultural communication it is important to highlight some of the most important topics of analysis and discussion consisting in the cultural differences between cultures like national identity, cultural identity, and cultural identification, nonverbal communication, perceptual differences (time, status, trust), gender identification (masculinity/ femininity), experiences of discrimination, individualism vs. collectivism, a sense of *otherness* when interacting in unfamiliar cultures, religions and ideological differences, negotiation of friendship and kinship, ethical questions, linguistic differences, code switching and others (Martin & Nakayama, 2010; Samovar & Porter, 2003). From the standpoint of a public relations professional tasked with creating messages for multiple publics and negotiating relationships among diverse stakeholders, it might be best to take a *generic approach* in order to understand public relations situations in the global environment (Kent & Taylor, 2011).

Public relations practitioners have understood that the first thing that one has to do before communicating about anything is to conduct research, whether the message is supposed to be created for an internal group like the stakeholders or for an external group like the stakeholders. *The generic approach* has been proposed by Kent and Taylor (2007) as a model for preparing for intercultural public relations situations because it emphasizes genuine understanding of cultures and communication rather than simply convincing to act as the practitioner wants.

According to the two authors, a public relations professional who is interested in communicating with intercultural publics should engage in six activities: (1) *identify features of the situation* – the practitioner needs to take a broad approach to understanding the rhetorical situation that happened before, to estimate what are the expectations of the public and which specific norms and values will influence public's interpretation of the message; (2) *identify the intended audience effects* – this is the step when it is important to clarify the goals of the organization's actual communication and trying to overcome ethnocentrism in order to understand others cultures and not judging them by our own cultural standards; (3) *clarify the motivational intent of the organization and publics* – the goal of the third step is to find where the interests of both the organization and the public intersect; (4) *examine how meaning is created* – suggests that practitioners should examine the archetypal or symbolic nature of language and communication in the culture and learn about cultural archetypes, heroes, villains, social and political leaders in order to be better prepared to succeed in intercultural contexts; (5) *examine strategic considerations* – includes issues such as respect for elders, the role of government, religious and social features, trust and perception of time and it is

equally important to understand the nature of the media system; (6) *use communication principles and theory to understand how culture influences organizations and communication* – is actually the most important principle highlighting that understanding theory, how people think and understand ideas and the process of meaning making is essential to effective intercultural communication (Kent & Taylor, 2011, p.56).

Contingency theory is based on the premise that there is no one best way of managing organizations and practicing public relations that is optimal for all situations and argue that different strategies and practices should be considered for different environmental contexts in order to find an optimal fit (Yoonheung & Glen, 2005, p. 173). The theory emphasizes situational and environmental factors that have an impact on how public relations are practiced and it has the potential to provide a more holistic picture of public relations practices by considering *national identity* and social and cultural factors.

Even though all these studies have been reporting that cultural differences have an impact on public relations practices (Kinzer and Bohn 1985; Kent & Taylor, 2011; Sriramesh & Verčič, 2013; Zerfass et al., 2008), in Romania few public relations practitioners are showing their interest in the role of nature of culture in the process of communication with the publics. But this is an idea to be debated in the following research sections.

Research questions

Given all this factors listed in the literature review and influenced mostly by the top management decisions, we have launched an empirical research in order to understand the most important factors that influence the communication strategy for Romanian brands. In order to find out, we have suggested the following research questions:

Q1: Which are the most relevant organizational factors that are influencing the online communication strategy for Romanian brands?

Q2: Which are the social factors that are influencing the online communication strategy for Romanian brands?

Q3: Which are the share between organizational factors and social factors when it comes to online communication strategy on the Romanian market?

Methodology

In order to address the issues at hand, a qualitative approach was applied. In the context of analyzing which are the factors that are influencing the communication strategy in Romania, we have conducted a qualitative study with focus on answering the research questions and generalizing new routes of development in public relations practice.

The study was conducted in Romania and was based on 10 communications briefs sent by MNC's digital managers to public relations specialists in order to build a communication strategy for their brands. The documents were selected by selective sampling based on one single condition – the communication brief to be dated between 2016 and 2017 in order to have the certainty of recent results in the practice of public relations. It is important to be noted that we had access to this documents through the partnership between a local digital agency and his clients (MNC's) and so the names of

the companies are confidential as well as the full content of the documents. If it is imperative to access the briefs in order to demonstrate the validity of this study, a special request will be sent to the researchers in order to verify the authenticity of the results.

Therefore, this phase of the study comprised a set of 10 communication briefs representing a cross section of brands with activity in areas such as food, healthcare system, beauty, financial system, software, entertainment, telecom or gas and oil. The literature review and the expertise of the members of the research team contributed to the development of a qualitative coding of selective quotations from the documents. In order to have an easy access to the big picture and revealing the meanings and the relationships between the codes we used ATLAS.ti, specially designed software for qualitative and mixed methods data analysis. Each communication brief was added to ATLAS.ti in order to identify all the factors mentioned in the document with the purpose to be considered in the online communication strategy built by the public relations specialists. Therefore, all documents were operationalized by using the factors mentioned in the literature review and their definitions. We need to keep in mind that the essence of the interpretative documents is reconstructed rather than being clearly identifiable. This limitation of the qualitative content analysis method derives from the ambiguity of language and epistemological boundaries.

Findings and discussion

Organizational key factors that influence online communication strategy for Romanian brands (RQ1)

When it comes to the question of which are the most important factors that influence the communication strategies of Romanian brands, the organizational ones are certainly the most often mentioned. Through *organizational factors* we are referring to the factors that depend by the brand only, MNC's being the only entity that could control variables. Each communication brief mentions an average of 9 organizational factors that could influence the message transmitted to the public. Which are the organizational factors that matter the most for the communication strategy of Romanian brands? Sorted by the number of mentions after coding the quotations based on the literature review, we reached the following factors: business objective, product, market, social insight, global influence, company dimension, competition, brand values and brand personality, brand history and local influence (Graphic 1).

All the documents analyzed mentioned an average of 4.4 business objective, which means that the purpose of communication is the most important factor when it comes to strategy. 9 out of 10 documents mentioned awareness as one of the main objective of the communication strategy, which means that, besides the fact that we're talking about international brands, the communication managers consider that the brands still have an awareness weakness in the market context (Graphic 2).

"Increase on both organic and paid reach" (Entertainment).

"Generate awareness for the problem and for the solution" (Software).

"Create awareness through social media" (Chocolate).

"Increase brand visibility and awareness" (Financial).

Graphic 1. Organizational key factors that influence online communication strategy for Romanian brands

On the other hand, 7 out of 10 companies wish to build a community in order to engage with the customers. This is the evidence that technological and social pressure force brands to constantly change their business strategy in order to establish a closer relationship with their publics.

“Establish a communication bridge between brand and his followers” (Financial).

“Build the everyday conversation” (Beauty).

“Create an online channel in order to engage with our customers” (Food).

The product and the market are important factors as well, described in the communication briefs, but we consider that it should be the center of communication without which no public relation practice would be possible. Instead, we would like to take a closer look to the *social insight*.

Only half of the briefs mentioned the social insight’s influence on the communication strategy. In order to build a strong message, we consider that it is imperatively important for the brands to understand the environment including the social context and the social behavior, which means having a social insight about the publics. Of course, by having social insights, the brands have to assume a role of researcher and be interested in knowing both their stakeholders and stakeseekers.

“I am buying online because I’m looking for promotions/discounts and sometimes prices are lower when one buys online” (Financial).

“I want to experience all that life has to offer and I work hard in order to achieve all my wishes” (Telecom).

“1 of 10 users who visit adult websites is younger than 10 years old” (Software).

Global and local influences are as well mentioned in the documents, but only in the context of the market share (global or local) and the brand history.

Graphic 2. Main business objectives

Social key factors that influence online communication strategy for Romanian brands (RQ2)

Social factors are referring to the variables that cannot be controlled by the organization because they are influenced by the external public of the brand only. Each brief communication mentioned an average of 6.1 social factors considered by the digital managers that could influence the communication strategy and, as a result, they are relevant for the brand. Based on the literature review discussed in the section above, we coded the relevant quotations from the briefs and identified the following social factors, listed by the number of total mentions: age, gender, consumer behavior and online behavior, education, demography, income, interests and user experience (Graphic 3).

All documents pointed out that the age of the targeted public is one of the most important factors when it comes to the matter of creating the main message of the campaign. It is followed by the gender, a factor that is referring to both males and females (exception for the beauty brand whose message is addressed to women only).

On the other hand, the research revealed that only 6 out of 10 briefs mentioned the consumer behavior, even if we are talking about online or offline behavior.

Graphic 3. Social key factors that influence online communication strategy for Romanian brands

“The consumers are now, more than ever connected globally, obsessed with sharing makeup experiences or products and driven by education” (Makeup).

"The consumers are interested in the health of the family, take care of them and wish for a normal life like they have seen abroad" (Health).

"The consumers think that having the latest products and services gives others a good impression on them" (Telecom).

"For the consumers, YouTube is the place to go when they want to learn the newest trends in makeup, Facebook is the online TV from where they find out about the newest things, whereas Instagram is a driver that captures the user's attention" (Makeup).

"The consumer would rather buy online because he can compare prices easier" (Financial).

"By developing social networks, the consumers are viewed as in trend by people in their community" (Telecom).

Age, gender, demography and education and the level of income are social factors that co-occurrence. The co-occurrence refers to the co-existing of two or more codes in the project; two coders are used on the same quotation and we can examine how many times they are co-existing helping us identify relations between the quotations. By coding the documents, we observed that social factors like age and education co-occurred in 6 situations while education and the level of income co-occurred in 4 situations, which means that half of the brands wish to communicate with the same target: 25-55 years, medium-high education, medium-high income.

"Target: men and women, 25-50 years, medium to high education, medium to high income" (Gas and oil).

"Target: men and women, 21-45 years, medium-high income, urban and rural with high education" (Financial).

"Target: 25-60 years, medium-high studies, incomes above average" (Food).

Table 1. Co-occurrence between age, gender, education and income

	Education	Income
Age	6	3
Gender	4	2

Which factors are most important when it comes to engaging with the external public (RQ3)

A look to the overall research results shows that organizational factors are more often mentioned than social factors. Experience shows that in Romania, companies are mostly focused on the business objective and don't have a holistic overview in order to consider all the factors that could influence the communication strategy for a brand. Even though all these studies have been reporting that social and cultural differences have an impact on public relations practices (Kinzer and Bohn 1985; Kent & Taylor, 2011; Sriramesh & Verčič, 2013; Zerfass et al., 2008), Romanian brands did not overcome the traditional public relations practices and continue to communicate with their public only by changing the message and the communication channel, not the brand strategy overall.

Table 2. The share between organizational factors and social factors

Age	6	3
Gender	4	2

Conclusions

Various materials have been collected in this qualitative study, which analyzed 10 communication briefs belonging to international brands with activity in the Romanian market. The study clarified a wide range of answers to questions referring to the factors that influence the online communication strategy in the Romanian local context. One of the results is that MNC's are not ready to invest in research in order to find the most valuable insights for their stakeholders. This shows that online communication is still a recent field in Romania, where MNC's continue to be interested in the organizational factors in order to achieve the business objective.

Nevertheless, our research was able to identify a number of overlapping issues which could be interpreted as cornerstones for developing a public relations function in practice and might inspire future research. This study could be as well interpreted as a wakeup call: technological and social pressure force brands to constantly change the business strategy in order to be relevant for their public. When the brand changes the communication channel it should consider to change the strategy as well based on a strong research about their stakeholders and their online behavior.

Throughout this study we were able to identify that the cultural factors have to be considered in the communication strategy because they are not even mentioned in the communication briefs written for the public relations specialists, even if communication influences and is influenced by culture (Sriramesh & Verčič, 2003).

Therefore, there is a trend to achieve the company's objective through mass messages send through online channels. This is considered to be a more effective tactic that implies fewer resources and brings higher results. However, it was not demonstrated how efficient this strategic decision is, considering the initial objective of the company and the fact that this strategy is based on unique messages. In addition, the pressure of the digital trends and technological innovations created a gap between the quality of the message and the pressure to send the message in real time. Everything has to happen *now*, and what today is new, tomorrow will be already old-fashioned. Therefore, user's behavior is changing constantly, influenced by the high number of changes implemented in the online channels and by the speed with which these changes are implemented globally.

In this context, the final purpose of the research will be to bring a new perspective upon the digital communication strategies in Romania, by identifying the most important factors that influence the final message from the brand to the client. Also, the results have the potential to contribute to a new future research and create a connection between the classical theoretical models of public relations and future new possible models, with focus on the communication channel and the characteristics of the targeted public.

Abstract. *For modern businesses, e-marketing strategy is required to establish the information flow. The relationship between the company and the customers by tracking the actual weight of channels preferred by the consumers and potential clients is becoming a priority at the present moment. Because the weights of the favorite channels are changing very quickly, tracking the actual weight of channels to the attention of consumers is not an easy objective to accomplish, and marketers need to understand the trends very well. Some companies hire people trained to provide a specific professional skill, and other companies are externalizing this service, depending on a cost-benefit analysis to find the proper approach. With the desire to get as close as possible to the customer, today's companies have made an important step by integrating online business efficiency tools and technology development. Developing customer relationship management based on personalized IT systems developed on business specificity and using socializing and promotion channels to increase visibility and online availability on all the customer's favorite channels is translated in engaging customers. Also, using the consumers' reviews in the process of developing/improving products/services is giving to businesses an advantage over the competition. Business management must constantly pursue the dynamism of the market according to the trends of the industry in which it plays, adapting the vision and the uniqueness of the business to the dynamism of the market. Recent studies about marketing programs in which companies are tending to invest anticipate a further increase in investment in 2018, on customer service management programs, which suggests that the business's intention to increase loyalty to existing customers is a core marketing trend for modern companies. This article will explore the link between e-marketing and the client, in order to identify the connections between them and to provide a theoretical model for improving the marketing process, considering the client's requirements. The aim of the proposed model is to improve the current marketing process implemented by companies through digital solutions to strengthen the relations between e-marketing and the client, after identifying the weaknesses the respective companies are facing.*

Keywords: *e-marketing; customer's requirements; digital technologies; online channels.*

Introduction

Digital marketing is a dynamic field where change is the leitmotiv. The change means adapting to the needs and demands of the market, but also streamline the way of choosing to respond to them. The development of technology and the fact that it is becoming more accessible in terms of learning and costs have led to its spread amongst marketers and consumers alike.

If 2017 was about the expansion of smartphones usage and interaction with VR, AR, and 3D printing, in 2018, all this gather together and dynamize the marketing. Consumers are equipped with smartphones and smart gadgets, connected to the Internet because their available time has decreased. Consumers are open to responding to those who speak their language in the environments they prefer and in real time.

New challenges bring new opportunities, and marketers can take advantage of them by taking into consideration a few aspects. The year 2018 is about consumers and how to deliver them personalized services and products. It is an important requirement to determine what and where to look for and exploit their micro-moment to place a trigger on the sales page.

Search engines learn from every use, thus collecting a lot of user data. Marketers only need to understand this information that stands in front of them. The future is represented by interactions that humanize the process of learning, documenting, socializing, and eventually acquiring products and services. In 2018, businesses should be in concordance with the needs and desires of their customers, who are motivated not by the intention to buy as much as possible but by the desire to experience as much as possible.

Thus, this article aims to determine the new e-marketing methods, as well as the relationship between them and the consumer. By establishing a more personalized profile of the consumer and his interaction with the technology, one can determine the ways through which it can be attracted to the acquisition of a product/service. Once these means to which the consumer is receptive have been identified, a digital marketing model can be developed to help the company grow on multiple levels.

Theoretical backgrounds

Numerous researchers have studied consumer perceptions, their relationships with companies, and the means by which they are targeted in digital marketing campaigns. Some of these concepts are elaborated in books written by authors like Shaltoni et al. (2018) who investigated how SMEs use e-marketing, Turban (2018), who talk about social commerce and marketing, Ali and Bani Hashim (2017), who analyze consumer satisfaction following e-marketing, but also by others who describe their analysis in scientific articles.

Bonetti, Warnaby, and Quinn (2018) summarize the current perceptions of Augmented Reality and Virtual Reality applications in the context of sales, including the reasons for their use in marketing. Marasco et al. (2018) investigate the impact of virtual reality experiences on websites and how to attract consumers in a certain direction. Scholz and Duffy (2018) carry out an ethnographic study to examine consumer and brand

relationships through Augmented Reality, focusing on the physical and the inner context of how self-augmentations are integrated into consumer self-concepts.

Marinchak, Forrest and Hoanca (2018) examine the state of Artificial Intelligence, focusing on marketing applications and new engagement rules. He considers that marketing will be directed to Virtual Personal Assistants, focusing on meeting the real needs of the user. Siau and Yang (2017) sustain that sales and marketing are influenced by Artificial Intelligence, robotics, and automated learning, replacing sales and marketing professionals in online stores. The research consists of a longitudinal case study to analyze the evolutionary nature of sales and marketing.

Sotolongo and Copulsky (2018) highlight trends that have contributed to the increased number of conversational interfaces and the implications of marketing conversational data. Thus, it can be noticed that through conversational interfaces, the needs of consumers are better satisfied. The Barwise and Farley's study (2005) shows that e-marketing is growing, but there is little empirical research about its impact on marketing and performance.

Tulk's invention (2018) consists of an Internet-based marketing method that correlates organizations and consumers of services through a simple mobile application. Papista et al. (2018) tested a model that included motivational factors for the relationship between consumers and brands, wanting to build customer value for a company. Waheed and Jianhua (2018) initiated a research to determine the link between e-marketing and consumer behavioral peculiarities. An important role in their decision to purchase products is given through online marketing.

Chaturvedi (2018) shows that today's companies have focused on owning a website to promote their product. In his research, 80-90% of the population is attracted to online advertising, especially to social sites.

Consumer profile - a determinant factor in implementing marketing strategies

The term prosumer is not a new one, it appeared in the '80s and represented the professional consumer, specifically targeting users of high-performance audio-video equipment. The online environment has, however, brought new valences to this notion, prosumer being today a *mélange* between the producer and the consumer. In other words, this consumer not only uses certain products but is also actively involved in the production processes, influencing the direction of company development and communication strategies. The prosumer has a distinct behavior that a company should know in order not to have unpleasant surprises. A prosumer is not only confined to consumer products and services, it will also talk about his experience with them and will try to influence the process of achieving them. The prosumer is a kind of unsolicited advocate of companies, who will articulate his opinions with frankness whenever he or she will feel the need publicly. Prospectors strive to be part of the production process. Every time, on a site, blog, Twitter or Facebook account, there can be seen user suggestions about the ingredients of a product, the way a service works or the design of some products. Prosumers are aware that they are informed and feel responsible to improve the products and services they consume.

The definition of a consumer profile refers to those data about habits, behavior, beliefs, and decisions that a buyer/customer has in relation to a particular product or service. Delivering a more accurate profile to the consumer is extremely important for both a business, a supplier of the product or service in question, and for the specialists in the promotion.

Getting to know better the client will give a precise perspective about what attracts him and makes him buy and use this information to better shape the product or service of a company according to consumer preferences. At the same time, using this information, promoters will know how to address their potential client and which communication channels they should use to arrive at the consumer faster. Therefore, here are the advantages of making a consumer profile as accurate as possible: defining the target (the consumer profile contributes to determining the main features of the business target), relevant and qualitative messages (include relevant customer information so that they are determined to choose the company's product rather than the competition), budget optimization (the channels through which a company can reach potential customers without testing different campaigns and promotion methods, but will go straight to the target with the right messages and communication channels used by them), creating a strong brand (when the customer is known, a company will have more chances to determine exactly what he needs and can deliver products and services accordingly. Having satisfied customers, the popularity of the brand will increase, which will lead to a strong image, well impregnated in consumer memory).

Elements of a proposed model user profile

After determining the need for a consumer profile, it is necessary to determine what data it contains. Broadly speaking, the consumer profile should be similar to the description of a real person, from age and geographical location to favorite socializing passions and networks. When it comes to creating a profile, it is important to follow:

- Consumer age range, gender and geographical location - even in everyday life. This information is equally relevant when trying to sell a particular product or service or transmitting a message about what a company delivers / supplies / produces.
- Occupation of the potential client is necessary to estimate important customer data, such as the level of studies he/she has, the average of the income he/she enters, the consumption habits.
- Preferences, habits, passions - the more a consumer is better known, the better is known what he wants. Information about what he likes/dislikes, how he spends his spare time or what his passions are, can be extremely useful when projecting a marketing campaign, for example. A company will know exactly what kind of images / information / messages will make him react positively.
- The features/benefits of a product a person would buy or a service to call - when delivering something to a certain audience, a company needs to know exactly what the public would like from the product or service that is offered to him. Therefore, a company needs to know the potential customer's claims in order to give him what he desires - an important decision-maker in the acquisition process.

- Where are potential customers - which social networks they use, what sites they visit, what kind of publications they read, or what information channels they use. Thus, they can be greeted with products and information exactly where they are needed, in a familiar and enjoyable environment for them.

In order to categorize all this information as easily as possible, a consumer profile kit has been created with customer-specific questions to help shape the person:

Figure 1. Model for consumer's profile

Methods of e-marketing – analysis

Social Media Marketing is growing in importance, but it becomes more segmented in 2018. In 2018 Facebook surpassed the incredible number of 2,000,000,000 users. (<https://en.wikipedia.org/wiki/Facebook>) Instagram, which is also owned by Facebook, will surely reach billions of users in 2018. (<https://en.wikipedia.org/wiki/Instagram>)

No business, and especially B2C, can afford to ignore the social environment. However, the results will be more and more difficult to achieve. Unless it is talked about a large brand that has a considerably marketing budget, the chances of achieving tangible marketing results through a wide-ranging campaign for everyone are nonexistent. The costs of promotion paid on social networks will increase and the organic impact will decrease. In order to have a positive return on investment in marketing, and to make the most of these platforms, there must be a more segmented strategy.

Augmented Reality (AR - Augmented Reality) has moved from a niche to a must-have technology, becoming the mainstream. In June 2017, Apple introduced ARKit, a tool for

software developers to help them develop iPhone AR experiences. Google soon released ARCore, the version for Android. By providing additional information to consumers about products until they are able to test them virtually, the applicability of AR can already be seen in the gaming, fashion, retail, and marketing industry.

AR causes consumers to interact more with products on the shelf in the store. Brands use AR technology to bring product labels to life and thus provide consumers with a fresh experience. Those interactive moments bring a new breath and help differentiate the product into the mind of the consumer. Interactivity generated by AR does not stop between store walls, passing them directly into the online. AR technology has the advantage of generating content in social media, improving word-of-mouth marketing strategy.

With the emergence of multiple channels of communication, marketers will be aware of the lack of distributional attention of consumers and will have to carefully choose where to do the promotion.

Virtual Reality (VR) - The spread of high-speed Internet access (5G) increases the demand for novelty technology features. This is also the case for Virtual Reality (VR) applications. By 2022, the total VR market will exceed \$ 26 billion, according to a survey by Zion Market Research. (<https://www.zionmarketresearch.com/news/virtual-reality-market>) Retailers, brands and service providers will have to rethink the strategy in the light of these issues.

Brands that offer 3D experiences will receive more attention from consumers. Advertising and the way in which sales are made will be strongly influenced by VR. Using the consumer's (or persona) profile, marketers will be able to place targeted ads in the 3D experience that the user considers relevant. VR already allows visual and audio experiences. The following senses that will be stimulated are the olfactory and tactile, practically a transposition into another reality. These upgrades will allow consumers to test and feel the products before they buy them. The VR is part of the future of retail. This will not only discuss e-commerce (electronic commerce) but also v-commerce (virtual commerce) or virtual commerce.

VR can also be used in e-retail. WebVR is an open-source tool to be integrated into your browser. The tool allows users to view 3D objects directly into the browser without having to download additional applications anymore. Basically, the user who wants to find out more details puts his 3D glasses that integrate the smartphone on which the product's image is displayed in the browser. The user can see the product from all angles, rotate it and even try its functionality.

The Statista published an estimate by 2018 of revenue from VR, software, and hardware (see Figure 2, p.115).

Figure 2. Virtual Reality incomes in the last four years (<https://www.brandweb.ro/blog/cum-imparti-placinta-pentru-a-fi-in-trend-in-2017-9-directii-pentru-bugetul-de-marketing>, accessed on June 15, 2018)

The trend is to bring online facilities directly into store shelves. Retail and technology will become inseparable. Artificial Intelligence, Virtual & Enhanced Reality, and the Internet of Things will make a significant contribution to customizing your shopping experience.

Artificial Intelligence (AI) has the potential to change the way organizations and businesses communicate and innovate. Any industry that operates with huge amounts of data, those sets of data that cannot be independently analyzed and interpreted by the human mind, can turn to AI. Of course, any industry that needs customer service will find appropriate solutions in AI. Already, in customer - talking with robots that solve problems. In the near future, these robots are expected to be emotionally intelligent, to have the ability to recognize and communicate emotions and feelings.

Figure 3. Predictions of AI usage (<https://blogs-images.forbes.com/louiscolombus/files/2018/01/Reasons-for-adopting-AI-Worldwide.jpg>, accessed on June 18, 2018)

Chatbot - Due to expanding Internet access and increasing the number of smartphone users, messaging applications have become a significant part of the mobile applications market, providing users with an alternative to SMS messaging. Messaging applications have enhanced features such as group chats or photo sharing. Mobile messaging applications are the ideal communication channels for consumers who are always on the move and want an instant response. Consumers want to know that their issues are important and that someone will immediately deal with their resolution. A chatbot has this ability to respond immediately and even to solve tasks that an employee should spend time on. Chatbot chats can be used in marketing as the first contact with customers and to collect their email addresses for subscribing to the newsletter, for example.

It can be seen that people tend to increasingly use mobile devices and applications that can be installed on them. Because of the lack of time, they are starting to increasingly prefer the activation of goods and services through the online environment. By offering attractive means to help them visualize their appearance, consider them a necessity that they must hold, they become consumers of certain brands. Thus, companies should identify their target market and focus on using these new marketing methods, which are preferred by consumers and who rely on their wishes to win and turn them into loyal customers. The following model aims to adopt the newest e-marketing methods, which are proven to be consumers' and enjoyable:

Figure 4. Model of using new marketing methods

The model proposed to find out as much information about the consumer is one needed to build their profiles, data that will be stored in a company database. These data are processed and used by the marketing department, which is essential in determining the methods and channels through which they can contact consumers. The company must also have a web page or website. Integrating chatbots into both social media channels as well as on the site and application facilitates communication with users, giving them quick information and helping them 24/24 hours. The VR, AR, and AI elements

contribute to a pleasant experience, helping people visualize products in a manner that is close to reality without moving to a physical location or remaining undecided or not.

Conclusions and implications / Discussions

The role of marketing in the market economy is inconceivable. Marketing combines the two fundamental functions of society - production and consumption and directs the whole economic activity to meet the needs and desires of consumers. Marketing has the role of providing the necessary information to market knowledge, bringing the company's technological capabilities to the needs of potential buyers. In addition, its relational character allows the establishment of credibility links between the firm and the environment, absolutely necessary for business success, transforming society's needs into business opportunities.

In any market economy and even in any competitive field, in order to achieve its objectives (profit, sales, market survival, etc.), the consumer occupies the central position. The consumer is the reference element for the actions of the suppliers of products or services, merchants. By purchasing their decisions, consumers determine the sales and profits of a company. In a competitive environment, the company does not survive if it does not study the consumer. Successful, profitable companies in market-economy countries are based on their consumer-related marketing strategies. To be profitable, an organization must first meet the consumer's needs: study it, understand its needs, wishes, motivation, and seek to achieve genuine consumer satisfaction.

Marketing is a field flooded with new technologies without which we thought we could not work. Sophisticated tools, digital strategies, and smart technologies make it easier for marketing people to make their choices more difficult. Technology creates new opportunities, for example, chatbots, facial recognition, image recognition and robotics. All provide marketers with information to train Artificial Intelligence and deliver personalized and geo-localized experiences, impressing their customers. These trends should not be seen as a must-have, but must of all be understood and filtered by the critical mind of the marketing man who finally chooses those technologies that support his business goals.

This paper proposes a model that helps to establish the level of consumer knowledge in order to develop a marketing strategy. We have identified new marketing methods that are growing in size and that have a positive impact on people in order to make them choose a product/service from a particular company to the detriment of another. Thus, once held information about consumers, as well as about the methods to which they are receptive and who attract them, a marketing model is proposed for companies, aiming at increasing the number of clients, sales, notoriety, turnover, brand consolidation.

Abstract. *Information Communication Technology (ICT) has reformed the business environment worldwide, providing retailers with expanded markets, while offering consumers a greater range of alternatives. It is thought that by the year 2050, e-commerce will break through all companies, and most of the business transactions on a global level will actually take place electronically. E-commerce is becoming the fastest growing form of commerce globally. One of the industries most impacted by e-commerce is tourism; tourism has become an information-intensive industry. Nevertheless, e-commerce is an essential component of travel and tourism sector and the use of the Internet for brand building is an increasingly common. When we talk about online marketing, we are mainly referring to e-mail marketing, search engine optimization, affiliate marketing, display advertising and Social Media, which is perhaps most prevalent in the tourism industry. In the given context, the aim of this paper is to analyze the impact of Social Media on consumers' behavior related to their travel choices, to investigate whether Social Media influence people's decision to visit specific tourist destination. The primary method used is an online questionnaire, along with documentary analysis, statistical analysis, and personal observation. The paper will start with a brief literature review to explore themes such as tourists decision-making behavior or motivation of travel. Then, the relationship between Social Media and the desire to travel, as well as the use of Social Media throughout the whole holiday decision-making process, including before, after and during the trip will be examined. Therefore, this paper investigates the influence of Social Media on the overseas travel choices of Romanian Millennial users, also known as Generation Y or Echo Boomers, the largest cohort of Internet users, often called digital natives, as they are the first generation born in the Information Age and for whom travel is a way of life. Plus, the paper also highlights opportunities for travel and tourism businesses to reshape and customize their marketing strategies to gain competitive advantage.*

Keywords: *UGC; Social Media; tourism; Generation Y; digital marketing.*

Introduction

Nowadays, the Internet represents such a tremendous opportunity for both businesses and consumers, but might also be a threat, “the increase in customer power and knowledge [...] the bargaining power of customers” being, perhaps, the biggest challenge posed by electronic trading (Chaffey, Ellis-Chadwick, Mayer, & Johnston, 2009, p.47), along with the too high level of competition (Schwarzl & Grabowska, 2015, p.190). One of the sectors most impacted by e-commerce is considered to be tourism that, according to the World Tourism Organization (2001), has become an information-intensive industry. Nevertheless, e-commerce is an essential component of travel and tourism sector and the use of the Internet (through online marketing tools and practices) for brand building is an increasingly common custom (Hudak & Kianickova, 2017), as “traditional (offline) marketing strategies are already widely used [...] and there are almost no new options for fostering competition” (Schwarzl & Grabowska, 2015, p.187). Hence, everyone should clearly understand the implications of online marketing for tourism, mainly the importance of e-mail marketing, affiliate marketing, and last, but not least, Social Media, which is perhaps most prevalent in the tourism industry.

Literature review

According to scholars, tourists’ decision-making behavior is a five stages process that goes from biological and physiological needs to safety needs, belongingness and love needs, esteem needs and finally to self-actualization that can be translated into personal growth and fulfillment (Schwarzl & Grabowska, 2015). As per Maslow’s Hierarchy of Needs which has been widely accepted and used to explain travelers’ behavior, the consumer’s “need” is the fundamental reason for making a purchase decision – it is rather a basic human requirement, like air or food.

When one realizes that this need exists, the “problem recognition”, often called “gap analysis” phase appears, this representing the first stage in the decision-making process. The second stage, “information search”, is very often met in the tourism-related buying decision. According to Chaffey, Ellis-Chadwick, Mayer, & Johnston (2009, p.7), “there is a dramatic difference in online consumer behavior in different markets”, and for the travel and tourism case, people usually research and then also buy online, while for purchases such as a house or a car, they only use the internet as a research tool. Stage three, “evaluation of alternatives”, brings out two essential concepts for marketing, namely brands and consumer value (Schwarzl & Grabowska, 2015). Consumers also buy products for what they communicate to them, for the “feelings” or “emotions” those products may create. Since travel and tourism is actually a service and not a tangible product, people, in fact, buy experiences and it is more often than not an emotional purchase, meant to satisfy belonging, esteem, and self-actualization needs. This idea is also supported by Pearce (1982), who made an experiment and analyzed 400 travel experiences of 200 tourists from USA, Europe, Canada, and Australia. These people were asked to describe one positive and one negative travel experience, and then he analyzed and coded their stories into five categories, as per Maslow’s pyramid. In the positive experiences case, self-actualization (35%) and love (33%) prevailed, while for the negative ones, safety (43%) and physiological needs (27%) came first.

Maslow (1970) also discusses two other human needs, which some scholars (Hsu & Huang, 2007) find more suitable in explaining some tourists' behaviors, namely the aesthetic needs, and the need to know and understand. People do travel to learn about something new, to be exposed to various kind of beauty, belief also sustained by Šimková & Holzner (2014), who found out that for Millennials at a Czech Republic University, "seeking personal rewards", "telling others about their new experience", "inspiration", as well as "escaping personal environments" are the main motives for travel. Moving further, we reach the fourth stage of the consumer decision-making process, often called simply "purchase", when potential customers "must decide when and where they are going to buy" (Schwarzl & Grabowska, 2015, p.192), a very important decision, that usually takes three to six seconds (Mooradian, 2012) and has recently started to take place online for tourism-related purchases, travel being "the leading e-commerce category in Europe by revenue for the fixed internet" (Chaffey, Ellis-Chadwick, Mayer, & Johnston, 2009, p.124). Last, but not least, "post-purchase-process", the fifth and last stage of the travelers decision-making process, as identified by Schwarzl & Grabowska (2015), rather refers to building and maintaining a long-term relationship with your customers, turning them into loyal consumers by understanding various key aspects such as how they used your product and for how long, or what feelings of satisfaction or dissatisfaction they experienced and how they intend to act next.

Lately, companies are also concerned about how consumers might create additional value for their touristic product, or about how often and when their products are in fact used until the ultimate disposal, furtherance called by scholars "customer-value chain" (Mooradian, 2012), that "shows highly important information concerning products' innovation and how to change customers' behavior" (Schwarzl & Grabowska, 2015, p.192). Yet, it is quite hard to define which advertising medium really convinced the customer and was, in fact, the crucial one for the final purchase choice, so it is very important for a company to know more about the conversion rate of their marketing means, to identify which are worth keeping or investing in (Bockhorni, 2014), given that, with the online marketing expansion, companies are currently offered an increasingly higher amount of possibilities.

Altogether, "nowadays it seems to be indispensable running a business without any online presence" (Schwarzl & Grabowska, 2015, p.195), especially since travel products and services seem to be well suited to online selling – they are "high involvement products [...] less tangible and more differentiated than many other consumer goods", these characteristics making them more appropriate to be purchased over the Internet (Garín-Muñoz & Pérez-Amaral, 2011). Furthermore, the Web is also shifting travel and tourism marketing practices from a B2C approach to a peer-to-peer model, mainly in what regards information sharing. Thus, a good understanding of the e-mechanisms designed for spreading information online can facilitate tourism companies to market effectively their businesses via the Internet.

In fact, one of the most important online tools used nowadays in Travel and Tourism is considered to be Social Media, "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content" (Kaplan & Haenlein, 2010, p.61), increasing the power of Word-of-Mouth (WOM), transforming it into electronic-Word-of-Mouth (eWOM), and expanding the potential audience beyond the traditional parties, family and friends, to new, wider, geographically dispersed networks of strangers (Lo,

McKercher, Lo, Cheung, & Law, 2011). According to the literature, “at the start of the process when inspiration is sought, the recommendations of family and friends (via social networking) are the most used source of information” (Rushton & Kennell, 2015), and, when compared to traditional forms of advertising, it was found that people trust eWOM more (Jamaludin, Aziz, Mariapan, & Lim Ain Lin, 2017).

One of the most comprehensive studies about the impact of online travel reviews on potential travelers was undertaken by Gretzel (2007) in cooperation with TripAdvisor – roughly 1500 TripAdvisor users answered an online survey. This project revealed that reading other consumers’ posts in Social Media was the most frequently used source of information and that users usually consider these UGC sites and social networking platforms more reliable, enjoyable and up to date than information presented on official travel providers’ websites.

In a top of vacation-inspiration sites, Facebook ranked first, with 29%, followed by TripAdvisor, that scored 14% (Carter, 2017), while Instagram is expected to get the lead in the near future, given that nowadays people engage with Instagram posts and stories ten times more than they do with Facebook (Miller, 2017). Even though people use Social Media mainly when looking for travel information research showed that they continue to use it also while they are on vacation or even post-holiday - while still traveling, 72% of people post pictures on a Social Network, and 70% of them update their Facebook status with travel-related information. Furthermore, after returning from a trip, 76% of travelers post photos from their travels, 55% like Facebook pages specific to the vacation they have just had, 46% post hotel reviews, 40% post touristic-attractions reviews, and 40% post restaurant reviews (Carter, 2017). Some other statistics are even more convincing for travel business interested in promoting their products online: as per a survey commissioned by Chase Card Services that reached 1002 travelers in the USA, aged 18-67, 97% of the Millennials share their travel photos, while 73% of them even post on Social Media at least once per day during the holiday, and 87% use Facebook for travel inspiration. In this regard, UGC can also impact the trip itself, as real-time images shared, for example, during some events, might often inspire others to attend attractions or events they had not initially planned. Of all the persons questioned, Millennials are more likely (44%) than other older-aged travelers (35-49 years old 28% and 50-67 years old 11%) to seek opinions on Social Media while they research a prospective holiday.

Methodology

There is currently still a limited understanding of how consumers use UGC sites for the decision-making process and the impact of these sites on travelers’ behavior worldwide, worthless to say that generations-wise studies on the topic are quite a few at the moment despite the rather prosperous times the travel and tourism industry experiences. While people appear to increasingly embrace these practices, the travel industry members and businesses seem to be skeptical about UGC sites benefits and also unsure of how to respond. However, any strategic decision to integrate UGC tools and features into a business should be preceded by comprehensive studies on how the UGC sites are being used by consumers. Our focus was represented by Generation Y travelers, as they are the most active Internet-users and we have explored the following research questions:

Q1: What role do UGC travel sites play in the decision-making process of Generation Y?

H1: UGC travel sites are mainly used during the information-search stage of the decision-making process.

Q2: How much do Generation Y consumers trust UGC compared to the traditional sources of travel information (official travel websites, travel brochures, email travel promotions, commercial operators, visitor centers, travel guides etc.)?

H2: Consumers trust UGC information more than other sources of travel information.

Q3: How important do Generation Y online consumers find the most popular forms of UGC information compared to other travel information?

H3: Various forms of UGC are considered more important than other sources of travel information.

H4: Consumers consider third party (i.e. non-commercial) sources of travel information less important than photos/videos posted on Social Networking sites.

To answer the aforementioned research questions and test the corresponding hypotheses, we have conducted a quantitative study and distributed an online questionnaire to a random set of 100 Romanian Millennial citizens, developed after reviewing existing literature up to date. Our survey took place in the period 27-29th of June; a web-link to the survey was distributed via Social Networking sites. A total of 80 completed surveys was collected from respondents. All data received was analyzed using SPSS version 20 and Excel. Thus, descriptive statistics, as well as regression analysis were used for this research.

The instrument consisted of seven sections, as follows: the first section focused on demographic characteristics, the second one was related to Generation Y travel habits and the third section concerned the Social Media usage by Generation Y. These three sections were made up of both multiple choice and single choice types of questions, but also one "short answer" part. For the next four sections, a 5-point Likert scale was used, ranging from a response of "1" corresponding to "I strongly disagree" to "5" representing "I strongly agree". Section four, five and six coincide with our hypotheses, while in the last section we added two more insightful questions, that enabled us to gain further understanding of the impact that UGC has on Millennial travelers' final trip planning decisions.

Results and discussion

The questionnaire was intended for respondents aged up to 38 years old, as they are representative for generation Y. The age of our respondents was mainly between 25-30 years old, and most of the respondents were Romanian women. Their occupations vary from students to economists, and 42.3% of respondents earn between 500-1000 EUR. More demographic data can be found in Table 1.

55.7% of the surveyed subjects take less than 5 trips during the course of a year, while 36.7% of them pursue between 5-10 trips and 7.6% travel more than 10 times/year. The majority travel both in Romania and abroad (81%), and the fact that more than half of the respondents usually take less than 5 trips per year can be linked with the fact that 63.29% of them have a disposable income of maximum 1000 EUR/month.

Table 1. Profile of Survey Respondents (Source: authors' work, based on survey data)

Age group	Number of respondents	% of respondents
18-25	26	32,50%
25-30	40	50,00%
30-38	14	17,50%
Gender	Number of respondents	% of respondents
Female	48	60,76%
Male	31	39,24%
Monthly income	Number of respondents	% of respondents
<500 EUR	17	21,52%
500-1000 EUR	33	41,77%
1000-2000 EUR	20	25,32%
>2000 EUR	9	11,39%

86.1% of the respondents travel for leisure and 93.7% opt for self-planned trips when booking a holiday, the services bought online being mainly transportation tickets (93.7%) and accommodation (84.8%), while 29.1% also rent cars or other vehicles.

The third section of the questionnaire concerned the social media usage - the most popular platforms are Facebook with 94.8% respondents and Instagram, with 85.7%, and the time spent on social media platform varies from 1 to 3 hours for 56.4% of the respondents, while 28.2% of them spend between 3-5 hours/day online. 15.4% spend more than 5 hours on these platforms, however not mentioned if the time spent is work-related.

The fourth section comprises questions related to the role of UGC sites in the decision-making process of a trip for a generation. Figure 1 summarizes our findings:

Stage of travel planning process	Question	Totally Disagree	Tend to Disagree	Not Sure	Tend to Agree	Totally Agree
Information search	I use UGC sites pre-trip when I had already chosen where to go	10%	5%	32.5%	27.5%	25%
Information search	I use UGC sites pre-trip when I search for ideas on where to travel	11.25%	10%	23.75%	35%	20%
Evaluation of alternatives	I use UGC sites pre-trip, when I evaluate the alternatives and try to narrow down the choice of destination	7.5%	10%	35%	28.75%	18.75%

Stage of travel planning process	Question	Totally Disagree	Tend to Disagree	Not Sure	Tend to Agree	Totally Agree
Purchase decision	I use UGC sites pre-trip, before the actual purchase decision, to confirm I had made the right destination choice	12.5%	17.5%	37.5%	16.25%	16.25%
Purchase (during trip)	I use UGC sites during the trip, when I try to find out information about specific attractions/activities	7.5%	10%	28.75%	30%	23.75%
Purchase (during trip)	I use UGC sites during the trip to share my experience with other travelers/friends	25%	20%	27.5%	16.25	11.25
Post purchase evaluation	I use UGC sites after the trip to compare my experience with those of other travelers	31.25	26.25%	26.25%	10%	6.25%
Post purchase evaluation	I use UGC sites after the trip to share my impressions with other people.	30%	21.5%	23.75%	10%	15%

Figure 1. Usage of UGC sites depending on the stage of the Trip Planning Process
(Authors' work, based on survey data)

According to our results, more than half of the respondents turn to UGC sites during the information search stage of the travel planning process. Also, most of them use UGC sites when trying to evaluate their alternatives pre-purchase and during the trip, in order to find out more about the local attractions and activities.

To enable Hypothesis 2 to be tested, we asked how much UGC sites are trusted compared to the other traditional sources of travel information. As it can be noticed from Table 2, UGC sites are trusted more (32% of the responses in favor of UGC, 24% prefer the traditional sources of travel information, while the rest 44% are not sure which source to trust more). A t-test also confirms that non-UGC sources are less trusted by prospective travelers than UGC sites ($t = 2.57$, $\text{sig.} = 0.006$). Among the traditional sources of travel information, email promotions and commercial operations seem to be less trusted compared to UGC sites, while visitor centers and guidebooks are the most trusted of the traditional sources mentioned, followed by official travel websites.

To test Hypothesis 3, where we assumed that various forms of UGC are considered more important than other sources of travel information we asked respondents to rank the importance of each UGC type (photos posted on Social Networking sites, videos posted on Social Networking sites, independent traveler reviews on travel-related websites, independent traveler blogs) and also non-UGC sources (state tourism websites, commercial operators, travel reviews written by professional travel writers, interactive travel planners, live webcams) on a 5-point scale, where 1 = I totally disagree and 5 = I total agree. We conducted t-tests to compare the mean importance scores for both

groups of travel information sources but also highlighted the percentage of respondents who indicated which of the components, UGC or non-UGC type, was more important to them.

Table 2. Trust in UGC sites compared to traditional sources of travel information
(Source: authors' work, based on survey data)

	Mean score	Totally Disagree	Tend to disagree	Not sure	Tend to agree	Totally Agree
I trust UGC sites less than any other traditional sources of travel information	2.90	8	17	36	13	6
I trust UGC sites less than official travel websites	2.75	8	28	26	12	6
I trust UGC sites less than travel brochures	2.66	11	25	27	14	3
I trust UGC sites less than email travel promotions	2.46	18	25	22	12	3
I trust UGC sites less than commercial operators	2.59	13	25	28	10	4
I trust UGC sites less than visitor centers	2.90	6	21	33	15	5
I trust UGC sites less than travel guides (guidebooks)	2.86	7	20	36	11	6

As shown in Table 3, consistent with our other findings and hypotheses, information provided by UGC sites was considered more important than that coming from non-UGC sources, the independent traveler reviews on travel-related sites such as TripAdvisor, Booking, or Airbnb are considered most important of the UGC sites, followed by the content posted on Social Networking sites. The only non-UGC source with a similar mean score as the UGC sites were represented by the blogs written by professional travel writers, which might also suggest how important blogs have become nowadays, no matter they have sponsored content or not. Blogs written by independent travelers, UGC source was also a popular choice of our respondents. The least important for Romanian Millennials surveyed were the information provided by state tourism websites and commercial operators, emphasizing the power of Social Media in this generation. 67.5% of the respondents consider travelers' reviews important or very important, 60% consider videos of places posted on Social Networking sites important or very important, 53.75% believe that photos of places posted on Social Networking sites are important or very important to them when planning their trip, and 51.9% assessed independent traveler blogs as important or very important for their holidays. On the other hand, only 13.75% of the Romanian Millennials in our sample think that information provided by state tourism websites are important or very important.

T-tests results also supported our hypotheses – when we compared the mean score on UGC's importance (mean = 3.62) against the mean score on non-UGC's importance (mean = 3.11), we noticed that UGC content is considerably more important to travelers than non-UGC sources ($t = 5.92$, $\text{sig.} = .000$). As such, both hypotheses H3 and H4 are supported.

Table 3. The importance of UGC and Non-UGC sites content for travel decisions
(Source: authors' work, based on survey data)

		Mean	Totally unimp.	Unimp.	Neutral	Imp.	Very imp.
UGC	Photos of places posted by real travelers on Social Networking sites (Facebook, Instagram, Twitter, Snapchat, Pinterest etc.)	3.53	3.75%	13.75%	28.75%	33.75%	20.00%
	Videos of places posted by real travelers on Social Networking sites (YouTube, Facebook, Instagram, Snapchat etc.)	3.61	3.75%	3.75%	25.00%	40.00%	20.00%
	Independent travelers reviews on travel-related websites (TripAdvisor, Booking, Airbnb etc.)	3.89	1.25%	3.75%	27.50%	40.00%	27.50%
	Independent travelers blogs	3.43	5.06%	13.92%	29.11%	36.71%	15.19%
Non-UGC	Information provided by state tourism websites	2.7	8.75%	30.00%	47.50%	10.00%	3.75%
	Information provided by tourism operators	2.8	8.86%	27.85%	43.04%	15.19%	5.06%
	Travel reviews written by professional travel writers	3.54	1.25%	11.25%	32.50%	42.50%	12.50%
	Live webcams from particular destinations/ attractions	3.3	3.75%	20.00%	32.50%	30.00%	13.75%
	Interactive trip planners	3.23	7.50%	10.00%	41.25%	35.00%	6.25%

As regards the final additional questions, the results in Figure 2 show that 55% of the respondents might make a final decision relating to booking a trip or travel product based only on the influence of UGC sites (33.75% chose they are likely to, while 21.25% would definitely make-up their mind relating to booking a trip based solely on UGC's influence). 31.25% were unsure what they would do, while 3.75% would definitely not base their travel choice influenced by UGC, and 8.75% stated they are unlikely to make a travel decision relating to booking a trip based on the influence of UGC sites. On the other hand, 27.5% might change their existing travel plans only because of the influence of UGC sites, and 13.75% would definitely change their travel plans after seeing certain

photos, videos or reviews in Social Media. Only 6.25% claimed that UGC sites will certainly not influence their existing travel plans.

Figure 2. Impact of UGC on Millennial travelers' final trip planning decisions (authors' work, based on survey data)

Conclusions

First and foremost, this research found that UGC has become very powerful lately, especially among the younger generations, and complements successfully non-UGC sources in what concerns travel information. In certain stages of the travel product buying decision, such as information searching, UGC sites have even started to replace non-UGC in Generation Y's buying behavior, far more of them using Social Networks, travel blogs, travel-related forums than official state tourism websites, travel brochures, or even interactive trip planners.

It is also very interesting to notice how the use of UGC changes throughout the trip planning process, UGC being a most used source of information at the beginning of the process while looking for inspiration and evaluating alternatives. Millennials use UGC quite often also during the trip when they want to find various information about the place they are visiting, but as the decision-making process moves on, our respondents did not seem to be willing to share their experiences with other people in Social Media. Yet, they trust more the information on Social Media, such as travelers' pictures, videos, or reviews than similar information from travel companies. The explanation for the intense usage of UGC during the initial stages of the decision-making process may be that the users want to fuel the enjoyment from anticipation, to confirm for themselves that they made the right decisions, but also to find out about various tips and tricks from other travelers, so to be prepared and get the most from their own holiday. Among the UGC sources, blogs are least trusted, but, when asked about the trust in non-UGC sources, professional travel writers ranked the highest, suggesting that Generation Y prefer to hear and read others' experiences (be they sponsored or not) than official, detached information about the destinations chosen.

This research brings up some key aspects for the parties involved in the travel and tourism industry – marketers should design strategies that combine UGC and non-UGC sources in ways that could make their brands better off, more trusted, reliable. People look for interactions with their favorite brands, want to voice their opinions and like to know they have been heard. They appreciate when real travelers are allowed to contribute to businesses' online websites and Social Network pages or when they can get answers to their concerns in minutes. Thus, there is a great opportunity for tourism providers to enhance their current e-commerce and digital marketing strategies by integrating various UGC functionalities into their existing websites, create a big community around their brand, be a voice in the online media. Yet, this may also be a challenge, and businesses should at least monitor carefully what people say about their brands online, as negative reviews could very easily damage their image. Marketers should rather work harder to boost consumers' engagement and increase organic reach through Social Networks, to make consumers join honest conversations than try to control and manipulate them through traditional forms of advertising – in the given circumstances, these latter tactics might actually lead to negative opinions about the brand. Furthermore, consumers should be encouraged to engage with the brands, to post reviews, opinions, share pictures, videos or any other form of content. Perhaps they should be reminded that others' opinions helped them decide about a certain destination, accommodation or tourist attraction, so they could also contribute and help others in return. Plus, incentives may be granted to users that update their profile and add as many personal information and preferences as possible. These would help businesses provide targeted content to the readers and also conduct webnographic research. Other add-ins, combinations of offline and online promotional sources, for example adding QR codes to brochures or flyers to boost call to action and raise awareness to online media means might also represent a suitable tourism marketing strategy for Generation Y.

Last but not least, regarding future research directions, it might be appealing to investigate if and how is the Romanian Millennial consumers' tourism behavior different than the counterparts' from abroad. Additionally, scrutinizing the reasons why some travelers still do not trust UGC sources might also be of interest, as well as how to increase people confidence in online content, how to increase users' engagement with your brand.

Abstract. *The world is surrounded by information. The main source of information is the mass-media, which helps people better understand the environment. Initially, the written or the broadcasted press has a considerable input on the public opinion formation, thus becoming a pillar for transmitting the image intended by the communicator to the users of the media channels. Currently, another important factor that influences people's opinion is the Internet. The technological ascension in the past few years has transformed the Internet into an alternative for information and interaction that is currently indispensable for all the population segments, but mostly for the youth. That is a reason to conduct research in this area. The main goal of this paper is to identify and carry out an analysis of future economists' perception and consider the influence of the mass-media on education process, in order to understand how they see the effects that modern media have on the development of their personality. The following theoretical methods were used in the research: textual analysis, document analysis and content analysis, the survey method, methods of data processing and statistical analysis. The survey part of the research took place from November 2017 until February 2018 and consists of more than 900 students' responses with economics specialization from universities in Latvia, Poland and Romania. This research brings new findings into this area by analyzing future economists' perception of relatively homogeneous groups such as age, cultural and training levels, the target groups belonging to European countries with similar social, economic and political experiences. The first main conclusion of the research is a synthesis of both aspects - the positive and negative - in terms of the influence the mass-media has upon the young generation that is hungry for knowledge, leaving the right to judge and action, and being fully informed. The second important conclusion is that nowadays the online reading is the mainly used mass-media. The results of research demonstrated a clear digital medium preference and in particular the Internet. From these findings, there are some lessons that can be conveyed to policymakers, teachers, parents and students.*

Keywords: *mass-media; information; internet; education; influence.*

Introduction

Modern society is called as the information society, which is due to technical and information advances. The great dynamics of change affect almost all aspects of social life. The ubiquitous technology requires new skills from the modern man to use it. Thus, learning is an indispensable element of existence that allows adaptation to unstable living conditions. (Marcinkiewicz, 2013, pp.46-53).

Taking into consideration the wide mass-media spreading over the contemporary society, it can be expected that it might has a major influence upon the citizens' education, being a potential mean of education and modelling for all generations. Consequently, a closer approach upon the ambivalent nature of the effects mass-media has upon the youth is quite vital.

The main goals of this paper are:

- identify and carry out an analysis of future economists' perception and consider the influence of the mass-media on education process,
- identifying the positive and negative influences that mass-media has upon the students during their education process,
- analyzing the conclusions resulted from the research and putting forward the recommendations.

The main research hypotheses are:

- H1 - the mass-media influence upon the youth is equally positive (if they know how to perceive it) and negative (if they are not aware by the associated risks).
- H2 - nowadays students mainly use the online reading.
- H3 - the Internet needs institutional regulations.

For research purposes were used the following methods: textual analysis, document analysis and content analysis, the survey method, methods of data processing and statistical analysis. The survey part of the research was consisted of questionnaire with grid-type closed questions, that took place from November 2017 until February 2018 and consists of more than 900 students' responses with economics specialization from universities in Latvia, Poland and Romania.

This research brings new findings into this area by analyzing future economists' perception of relatively homogeneous groups such as age, cultural and training levels, the target groups belonging to European countries with similar social, economic and political experiences.

Literature review

It can be said that in literature is a research gap in studying the influence mass-media and Internet on education process for young people – in study age. The literature review was conducted using an electronic database Scopus, WEB of Science and EBSCO. Three groups of key words were used:

- mass-media influence, internet influence
- education, students
- information, manipulation, positive, negative.

For each search a key-word from each group was used simultaneously. The limitation of study was the fact that the publication had to be written in English.

Some most publications were concentrated on health and human body (Heewon & Jisu, 2017; Jenny & Grady, 2014; Mahrokh et al., 2018). Some was concentrated only on children influence and behavior (Berson, 2008; Lieberman, Fisk & Biely, 2009; Wazir, Kamal & Manzoor, 2015; Zapesotskii, 2011). Only few publications are concerning about mass-media influence on education (Ershteyn, 2016; Florescu, 2014; Ilie, 2016; Thompson, 2017).

All along the years, the mass-media influence increased and became more and more powerful due to the technological evolution, from telegraph, radio, newspapers and Internet. It plays a crucial role upon the education of the young people, being a more and more accessed modality of getting information, that are more or less useful to the people.

A study accomplished by UNICEF in 2013 indicates that 90% of the teenagers are daily watching TV and that 50% spend more than 3 hours doing this activity, time that otherwise could be used for socializing or doing other activities with a more instructive profile. The same study shows that 88% of the teenagers use the internet, on average, for 3,37 hours per day, mainly for social networks. Over 50% of the youth that use social networks, do this for being in contact with their friends and just 1% use the social media for finding more about the risks they are facing if they consume alcohol and drugs. For the youth, the information found on social networks have a low reliability degree, the data resulted from the survey indicating a very low level of trust in such networks. This difference of opinions represents actually the starting point of this research.

In early 2017, 78.5% of the population aged 16-74 in Latvia regularly (at least once a week) used the Internet according to Central Statistical Office data (CSP). The proportion of Internet users in different age groups is significantly different. If between 16 and 44 years of age almost everyone or 96% of the population regularly use the Internet, then those at the age of 45-64 are 71.3%, while in the age group 65-74, only one in three (35.5%) at least once a week used the internet. But in accordance with Gemenius data in March 2017 82% of inhabitants in Latvia were using internet (Gemenius).

In Poland, according the information from Central Statistical Office of Poland 80.4% households have an access to Internet. In 2017, 67% of the population regularly (at least once a week) used the Internet (CBOS). Between 18 and 24 years of age 100% of the population regularly use the Internet, at the age 25-34 are 96%, 87% between aged 35-44, 70% between 45-54, 47% between 55-64 and 23% of population in the age more than 65.

According to a research of the Romanian Joint Industry Committee for Print and Internet (BRAT), as cited The Romanian Press Agency Agerpress.ro (2015), approximately 70% internet users out of the total population between 16 and 64 years old.

As the study reveals, from an environment initially considered a high-end one, mainly accessed by educated young people living in big cities, the Internet became accessible to a larger and larger category of population.

In accordance with Jomah et al. (2015), there is an impact of the boom in digital data in knowledge codification. The current status shows that 80% of the respondents are interested in learning via electronic devices, followed by e-mails at 75%. Also, 70-72% of respondents opt for video clips and sound and voice recording. 65% of the respondents selected images followed by graphical display at 61%. 50% of the respondents selected Journals. Further observation from the figure reveals that books and reference volumes had a very insignificant impact, as expected by merely 45% and 30% of the respondents. This directed us towards the necessity for micro learning, and encourages the increase of the usage of electronic devices. Micro learning concepts, based on mobile web learning, lead to a modernized education system.

Pătruț (2016, p. 84) emphasizes that: "Thousands of users are involved in creating the online encyclopedia Wikipedia, writing blogs, exchanging video materials, music or photos, collaborating, communicating, commenting, evaluating etc. The users' goal is no longer consumption, but generation and distribution of new contents, the newly arrived concept being that of participatory web. This allows for new forms of social interaction and communication organized directly by the users via blogs and social networks. Social communication of the type "a few producing for the many" has been replaced with the "many to many" type of communication, the final result being the creation of a virtual network of people connected on a social and global level". It means that social media can be a source of information and manipulation.

Ilie (2016, p.432) indicates that „taking into consideration the educational impact of mass-media, which exert a growing influence in modern society, educational communication should be given a particular significance, because it must become the all comprehensive tool that will help the taught to integrate, structure, analyze the information already acquired”.

Thompson P. (2017, pp.257-270) conducts research which suggests a negative relationship between frequent use of communication technologies, such as text messaging and social network sites, and academic performance. This study does not prove a causal relationship; it provides more detail on the specific study skills challenges students may be facing when they interrupt their studying with frequent online social communication. This increased understanding can help educators tailor study skills interventions and support more directly to students' needs.

Florescu (2014, p. 350) identified the main aspects of the media influence on education and proposed recommendations based on the conclusions stated. Florescu (2014), Ershteyn (2016) and Treapăt (2017) concluded that mass-media influences a society on all the channels that it has, in both positive and negative way.

The research methodology

In order to achieve the intended main goals and verify the research hypotheses was decided to prepare the survey method. The results obtained have become a basis for using methods of data processing and statistical analysis.

The design of the questionnaire consists of 12 questions that aims to gather information from the target group for a qualitative research. The target group of research was formed of 312 students on Faculty of Business, Management and Economics University

of Latvia in Riga in Latvia, 302 students on Faculty of Management at the University of Gdańsk in Poland, 300 students at the National University of Political Studies and Public Administration (SNSPA) in Bucharest, Romania. In addition, students specializing in economics, were selected to make research more focused on representatives of future labor market in financial area. The students can choose only one answer to each question.

The targeted group of this qualitative research has, as a common denominator, the relative uniform age, the high intellectual and cultural level of the selected subjects, interest in economics studies, but especially their need to permanently inform themselves. For the students, the contact with the transmitted information via mass-media is a necessary and objective aspect, and accessing the internet became a daily habit of every young person nowadays.

Results and discussion

Further on, it would be presented the questions and the interpretation to their answers.

Figure 1. Question 1: Which is the media channel you are mainly using?

In Latvia 100% of students are using internet as main media channel (Figure 1). In Poland, the most used media channel is internet - 99% answers from respondents, only few students are using TV. According to the respondents from Romania, the most used media channel is the internet, the rate being of 87%, followed by TV with 11%, the radio and the written press having insignificant ratios of less than 1%. Despite the good average global peak connection, Romania ranks 10th in the world at Internet speed, as shown by the Akamai (Q2, 2016 Report), however, Romanian students also use the other media channels than the internet, which shows an option for the diversity of information sources.

This result indicates the fact that the online environment is the most accessible for the youth, granting them the possibility to inform themselves, to socialize, but also to have fun. The connection to the internet is extremely accessible in the present times, positioning the TV on the second rank among the preferences of the questioned students, as this channel does not offer as many benefits as the social media.

These findings confirm our H2, that nowadays students mainly use the online reading.

Figure 2. Question 2: How much time do you spend on the favorite media channel, during one day?

In Latvia 39% of students spend between 1 to 3 hours using Internet and 22% less than 1 hour (Figure 2). In Poland almost, half of the students spend between 1-3 hours daily using internet and only 9% less than hour. 40% of the questioned students in Romania spend less than three hours surfing the internet and 36% out of these less than one hour.

The data demonstrate that the majority (about 60% and more) of youth are quite efficient and do not waste so much time searching for information. The result suggests also various other ways of spending the spare time and the balance between the online and the offline activity. For the youth spending between one to three hours on the internet, there is a moderate risk that it would become chronic.

It should be mentioned that more than 3 hours in front of computers or smart-phones, spend time 39% from Latvia and Poland, 24% students in Romania. It may for sure state that the latter are wasting precious time, which should be used for education, for reading books of general culture. The influence of mass-media in such cases is rather negative, both upon the culture level but also raises significant risks for the physical health, as well.

Distance education also using internet and electronic devices. Users of this kind of learning need (Vasilevska et al., 2017) necessary skills to use current information technologies, knowledge about basic means of educative resources on the Internet, skills that are necessary to be able to accomplish tasks assigned by teacher with the help of educative resources on the Internet.

On figure 3 is presented that most of the questioned persons (52% in Latvia, 42% in Poland and 43% in Romania) consider mass-media as a source of information, this aspect indicating the people's need to value, control and supervise the environment by accumulating information. The respondents that see mass-media as a main source of information are used to evaluate the environment based on the information they receive in a facile way, little filtered by own judgment or at all.

Figure 3. Question 3: In your opinion, mass-media is:

A significant percentage, almost one third, of the respondents consider mass-media as a mean of manipulation. That means that these admit mostly the negative parts of mass-media and less the positive ones. While 13% respondents in Latvia, 25% in Poland and 19% in Romania consider mass-media as a mean of relaxation by which they can escape the day-to-day stress, and only 3% (Latvia, Poland) and 9% (Romania) consider mass-media as a mean of education.

It cannot be ignored that one third of the responses indicates the fact that mass-media has a manipulation impact upon the young people's opinions. It is extremely important that the students acknowledged this danger, namely that the mass-media is "a two-blade sword for Generation Z, born on internet", as Treapăt (2017, p. 1) showed. He argues that media "on one hand, it forms, on the other hand, it deforms. It is up to us to learn how to use this tool and this study can be useful for such learning." Same important is the fact that they consider mass-media as an education factor just in a small proportion, which is, in fact, true.

Figure 4. Question 4: Do you consider the information from mass-media, trustworthy?

Figure 4 presents the perception of the respondents upon the information's trustworthiness as provided by the mass-media is neither good nor bad, as 43% in Latvia, 51% in Poland and 44% in Romania consider the ranking as „Neither big, nor small”, when they refer to the credibility of the information they access through mass-media, fact that might

sometimes mean a lack of trust. The students obviously need information, but it is good that they are reluctant to what they get, being aware that the information must be filtered, verified, framed and assessed and only after that considered and used properly.

A huge percentage of respondents in all countries do not trust the credibility of the information received through mass-media at all. Only 7% students in Latvia, 5% in Poland and 21% in Romania consider this information to be trustworthy. These percentages, that rather suggest a lack of decision, prove that there is a certain influence of the mass-media upon the youth during their education process and that the results of such a research may lay at the basis for identifying some measures that enhance the positive influences and reduce the negative ones, such as manipulation, as much as possible.

Figure 5. Question 5: Does the information accumulated through mass-media determine a change in your attitude or behavior?

In what the influence upon the youth's attitude and behavior concerns – for the ones using the media channels it could be observed that of respondents in three countries do not consider that they are dramatically influenced by the information received through such means, so that it produces an attitude or behavior change – 48% in Latvia, 55% Poland, 39% Poland (Figure 5). The weight for the response „In a big proportion” is of only 8% in Latvia, 5% in Poland and 7% in Romania for this question, aspect that is not bad at all as, also considering the conclusions that were drawn for the previous questions, the manipulation, the entertainment and the irrelevant information are not a proper base for changing the behavior, but only for those who do not have enough life experience to judge/separate the good from the evil.

Figure 6. Question 6: Would you allow your child to use the media channels as a source of personal development?

On figure 6 is presented that most of the respondents in these countries chose the option according to which they wouldn't allow their children to use the media channels as a formation source. This aspect evidences that the young students preponderantly identified the negative effects that the media has upon the children's education and are aware about the impact these have in their formation. Also, the decreased percentage of 5%, 10% and 4% - representing the ones that consider mass-media as an appropriate source of formation evidence the majority's reluctance towards the messages transmitted through mass-media. It should be acknowledged that these messages are also consistent with their answers and with the previous conclusions.

Figure 7. Question 7: What influence do you consider mass-media has in the educational process?

Almost two third of the respondents considered that mass-media has both a positive and negative influence in the educational process (Figure 7). Consequently, mass-media may generate both beneficial and negative effects upon the educational process.

Although 14% of the respondents from Latvia, 11% from Poland and 27% from Romania considered that mass-media has negative effects upon the educational process exclusively, and 28% in Latvia, 19% in Poland and only 6% in Romania stated that it exclusively has positive effects. Once again it could be remarked the impact of mass-media upon the educational process concerns. The students preponderantly identify negative aspects and it is desirable to enhance the benefits that these media channels offer to the youth, under the condition to be correctly identified. Or, this is exactly the importance and the value this study brings.

Research results confirms H1 - The mass-media influence upon the youth is equally positive (if they know how to perceive it) and negative (if they are not aware by the associated risks).

On the question: „Do you consider that the information broadcasted through mass-media has to be subject to a higher degree of filtration?” a considerable percentage from the respondents answered positively (65% Latvia, 74% Poland, 77% Romania) (Figure 8). Consequently, the mass-media „consumers” are aware that the information received are not carefully selected by the specialists, and this deliberately sometimes. The filtration of the information involves the eliminating the data that are not objectively describing the reality, misinform, and are not cut for the receiver's understanding. It is true that, in the Latvian, Polish and Romanian mass-media such filtration is sometimes done according to political likes or dislikes, selecting subjects for thus defending certain interests. The information filtration involves also presenting some ideas from various

sources, so that the receiver may see all the sides of a controversy and to choose for himself what to believe and what not to. The mass-media must allow the consumer to make his own choices and not to present him or her single alternative, but for this, the sources have to be carefully selected.

Figure 8. Question 8: Do you consider that the information broadcasted through radio, TV or written press have to be subject to a higher degree of filtration?

Figure 9. Question 9: Do you think that the internet needs an institutional regulation?

Answers' capitalization for question 9 is presented on figure 9. The respondents chose „Yes” option (47% in Latvia, 36% - Poland and 70% in Romania) for this question, highlighting the fact that the „freedom” in the on-line environment comes as a package with certain minuses and an institutional regulation could or, at least, should lead to a decrease of such disadvantages. Only in Poland students indicate in huge percentages that institutional regulation is not necessary. Nevertheless, the student's answers confirm H3 - the Internet needs institutional regulations.

All that is left to be done is to work on the quality of the persons that are nominated as regulators for this field. It should be highlighted again the role of the youth, in full formation process, as future specialists or at list as opinion moderators, not just as simple informational maneuver mass.

61% respondents from Latvia, 66% from Poland and 84% from Romania consider that an increased number of cultural messages would help to improve the education degree among the young persons, while 17% and accordingly 9% of the questioned ones do not consider this being a method that favors improving the education among the young

population. Percentages of answer „I do not know” indicate that respondents cannot appreciate the impact the cultural messages have upon the youth’s education or do not (Figure 10).

Figure 10. Question 10: In your opinion, an increased number of cultural messages/events would help to improve the education among the youth?

The role of the mass-media is, for sure, very important in shaping the young generation’s solid cultural values and also as good citizens, as well educated persons, values that are expected to already exist at the age the interviewed students are. Anyway, the essence of the question is whether we need more cultural messages in mass-media. The answer is unquestionably: yes. Mass-media has to increase the good impact of the culture among the young consumers of information.

Figure 11. Question 11: Gender

A percentage of 89% from the respondents to questionnaire from Latvia, 94% from Poland and 80% from Romania are aged between 18 and 25, whilst 10%, 4% and 14% are aged between 25 and 30 (Figure 12). In what the gender concerns, in Latvia and Romania 67% are females and 33% males, in Poland 73% are females and 27% males (Figure 11). From the sociological and statistical point of view, the results are reasonably corresponding to the student’s profile attending this university and do not influence the quality of the answers.

Figure 12. Question 12: Age - years old

Conclusions and implications

Most respondents use the internet as medium, about 1-3 hours per day and even more. Almost half of respondents consider the media a source of information, and just under a one third believe that this is a means of manipulation. Respondents do not trust the information they receive, they believe it are not credible and do not cause a change in their attitude or behavior.

Using students' answers to question 2 in this paper, but also many other studies (Singer & Alexander, 2016, pp.155-172) show that although young people prefer to read online, they actually remember much better when reading text. It is just an illusion that you will read faster or more comfortably online, being shown in numerous studies, as we have mentioned before, that key information, the most important ones are lost on the Internet or on tablets. Some key findings emerged that shed new light on the differences between reading printed and digital content. Students overwhelming prefer to read digitally, because reading is significantly faster online than in print. Students believe their comprehension as better online than in print, but, paradoxically, overall comprehension was better for print versus digital reading. The medium (on line or printed) did not matter for general questions like understanding the main idea of the text, but when it came to specific questions, comprehension was significantly better when participants read printed texts.

Results of the research demonstrated a clear preference of our students for digital medium and in particular for Internet. From these findings, there are some lessons that can be conveyed to policymakers, teachers, parents and students in what the mass-media influence upon the youth's attitude and behavior concerns.

In addition, a lack of trustworthy in the information delivered by media channels shows that more than half of the respondents would let the child only to a small extent of the media as a source of information. The influence the media can has is both positive and negative, but mostly negative from the responses. The questionnaire revealed that the internet needs regulation to filter information displayed and that a larger number of cultural messages can help educate young people in a positive way.

The major role of our research is to confirm that the media today is basically confusing with the Internet, at least for young students, and the duty of teachers and researchers could be to create a strategy to optimize media influence over users. By optimizing, we think about reducing negative influences in favor of those that are favorable. In order to put this strategy into practice, we need to first determine the positive and the negative factors. As 42-52% of respondents see the media as a source of information, it is clear that the strategy should also focus on the positive aspects of the Internet. It is true that the internet has numerous negative effects, such as fatigue, social isolation, etc., but it is currently the main source of information that provides quick and cheap access to information, contains many sources.

The first main conclusion of the research is a synthesis of both aspects - the positive and negative - in terms of the influence the mass-media has upon the young generation that is hungry for knowledge, leaving the right to judge and action, and being fully informed. The research confirms hypothesis H1.

The second important conclusion is that nowadays the online reading is the mainly used mass-media. The results of research demonstrated a clear digital medium preference and in particular the Internet. From these findings, there are some lessons that can be conveyed. The current study will provide valuable policy implications to policymakers, teachers, parents and students. It is confirmed hypothesis H2.

It is also interesting that students confirm hypothesis H3 that the Internet needs institutional regulations.

Although, all three hypotheses were validated, it should be highlighted that the analysis was carried out in countries with similar social, economic and political experience. The next question is: "Do the similar conclusions appear when into comparative analysis will be included students from Western European countries?"

Mass-media affects future specialists in economics, on their critical thinking and perception. What is interesting that in all researched countries many conclusions of the research are similar. It can be also a proof for globalization of the young society.

Beyond the scope of this study, future research can be conducted on the following foundations: the first - the future research can develop an advance mechanism to compute the influence of the mass-media on education process; the second - the scope of the study can be extended over a longer period and for other countries of the world.

THE NEW ERA OF PERSONAL DATA IN EUROPE: HOW CAN COMPANIES COMPLY?

George- Cristian IOAN

Babeş-Bolyai University

7 Sindicatelor St., 400029, Cluj- Napoca, Romania

georgecristianioan@gmail.com

Abstract. *Enforcing the EU Regulation 679/2016 seems to be a lengthy process, that will change the landscape of the European commerce. Adapting to the Regulation entails several obligations that any data processor must abide by. Respecting these obligations is a challenge that implies several changes to the corporate structure and internal policies and procedures. Protecting personal data is a costly affair and erroneous implementation of procedures, that leads to data leaks, can be harshly sanctioned. Given the large definition of personal data, maintained by the Regulation, it can be assumed that, even if a company does not directly process information of personal nature, it will encounter, at some points in its activity, incidental forms of data processing. For example, even if a firm's lucrative revenue can mainly be attributed to buying and reselling engross, the company will still process user data on its website. There are several steps that any data processor must comply with. These include a preliminary audit for assessing the quality of current data handling procedures. In this sense, data controllers that already had procedures in place to enforce the legal obligations imposed by the Directive 95/46/CE will be in a privileged position. However, market surveys show that very few processors have actually done so. Given that any real implementation of the GDPR is dependent upon a proper preliminary audit, this study will analyze the proper manner in which such an audit must be conducted. Erroneous preliminary assessments will inevitably lead to future violations of the Regulation. Secondly, after the initial assessment, internal procedures for data handling must be put into place. Clear codification is essential in this process. The processor must ensure that all employees that handle personal information of clients and commercial partners are well trained and able to understand exactly what they must do. Moreover, the procedures should not be limited to mere day to day tasks. Crisis scenarios must be addressed, as this can first of all limit the potential damage and ensure that the subjects of data processing are properly informed, in accordance with recital 85 of the GDPR.*

Keywords: *personal; data; European Union; GDPR; DPIA; DPO.*

The nature of the Regulation 679/2016 and the main changes

As of 25th of May 2018, the European Union's new framework of data protection will enter into force. Although data protection is by no means a new concern for the European legislator, even in itself, replacing a Directive, namely Directive 95/46/CE with a Regulation, the General Data Protection Regulation 679/2016 (hereinafter, the GDPR), creates significant changes in the landscape of personal data. As Regulations are mandatory second legislation tools, the provisions of the GDPR are directly applicable to both vertically and horizontally in any member state of the European Union. Thus, any data subject can submit requests to any controller that has access to his data based on the Regulation itself, with no regard to the national legal framework. Moreover, controllers can be held liable for any violations of the Regulation even if its provisions are yet to be adapted in the national law.

Changes of paramount importance are made as far as the substantial regime for processing data is concerned. These include (i) the establishment of obligations to appoint a Data Protection Representative and a Data Protection Officer; (ii) modification of the consent regime; (iii) express codification of the right to be forgotten; (iv) introduction of the obligation to notify the data subject and the authority of the breach of personal data security; (v) the obligation of transparency with regard to internal data processing procedures; (vi) the introduction of fundamental principles and new rights and (vii) the establishment of a single supervisory authority, with the modification of the sanctions regime.

Companies that actively participate in the European trade market must find manners in which to comply with the exigencies of the Regulation. Although this task is by no means an effortless stroll, it seems that data controllers that already instilled internal procedures to comply with Directive 95/46/CE will be in a significantly better position. Adapting to the Regulation is far better than starting from zero as far as data protection is concerned, as many of the rights and obligations the Regulation codifies either already existed, under the Directive or could have been easily derived from the Court of Justice of the European Union's case law. For example, the right to be forgotten already existed, ever since the famous Google Spain case, even though the Directive did not expressly mention it. Now, the same right is codified under the Regulation. It is easy to see how transitioning from a proper program of protecting rights under the Directive to fully functional internal procedures of GDPR compliance can and should be a rather smooth process.

However, the vast majority of companies are not in such a privileged position. According to a survey (Curtis, 2017, pp.7-8), out of 400 of the leading companies in their fields, only 8% of managers declared themselves ready for the entry into force of the Regulation, with 28% unaware of it. Another 26% said they would not be able to complete their internal measures by May 2018. Accordingly, the main focus of the present study will be to analyze the manners in which such companies can create compliance programs.

The premise of this study is that almost all low and middle tier companies will process data in some form during their activity. Processing is defined under Art. 4, para.2 of the Regulation as any operation or set of operations which is performed on personal data or on sets of personal data, whether or not by automated means, such as collection, recording, organization, structuring, storage, adaptation or alteration, retrieval, consultation, use, disclosure by transmission, dissemination or otherwise making available, alignment or combination, restriction, erasure or destruction. From the outset, it is clear that the European legislator intended to maintain a large scope of protection for the Regulation, building upon the blocks set under the Directive 95/46/CE. As such, merely storing employee personal data is a form of data processing. Almost any online activity will also raise questions of compliance. Even if ad-related profiling is not in place on a certain online platform, processing data such as a user's IP number, MAC address, information concerning his online account or persona or using cookies fall under the scope of the definition of data processing set forth by the Regulation. Recently, the Court of Justice of the European Union, in the case of *Unabhängiges Landeszentrum für Datenschutz Schleswig-Holstein vs Wirtschaftsakademie Schleswig-Holstein GmbH*, decided that responsibility for protecting personal data arises even when using a third-party platform, such as a Facebook fan page account. Moreover, even companies that reside outside of the EU, but

process data of European citizens have to find ways in which to comply with the GDPR, which some (Codevilla, 2018, p.12) regard as an important challenge.

General steps for implementing the GDPR

The first step in the process of adapting company policies to fulfill the standards imposed by the GDPR should always be conducting an internal audit (Khan, 2016, pp.7-8). In order to know what steps must be taken the controller must be aware of the current state of affairs in the company. In this sense, this would be an ideal moment for conducting the preliminary steps for a future Data Protection Impact Assessment, that would be carried out under the supervision of the Data Protection Officer (Voss, 2016, p.804). Secondly, the controller should verify whether the conditions are fulfilled for the mandatory appointment of a Data Protection Officer. Accordingly, changes should be made in order to comply to this obligation, whether that means externalizing this service, hiring a data protection officer or changing the work contracts of an already existing employee in order to encompass such responsibilities. Nevertheless, it is mandatory to appoint a person in upper management to supervise the process of implementing the Regulation.

Thirdly, internal procedures should be codified, concerning the handling of personal data. These procedures should not be generic and must actually take into consideration the nature of the processing and the types of data that are being processed. The philosophy of implementation should be that of data protection by design (Varotto, 2015, p.79). Sensitive data should be distinguished from normal processing. All employees that have attributions that either explicitly or implicitly involve data processing should be briefed and trained to respect the new procedures. Nevertheless, at this time, procedures should be instilled in dealing with Personal data breach notification, taking into consideration all potential breaches and possible worst case scenarios. The second part of reforming internal procedures should consist of ensuring that personal data of employees and other contractual staff are properly stored and protected. In this sense, it is essential that their consent is taken concerning upcoming processing necessary (Bevitt & Stack, 2016, p.12). Special attention should be given to situations where CCTV cameras are used in the workplace, during work hours, since they gather biometric data, which is a special category with higher standards of protection.

Lastly, the final step should be ensuring that the contracts used with third-party use proper means of obtaining consent for data processing. The Regulation significantly changes the legal regimen of consent, which must be express and cannot be deduced from other factual circumstances, as controllers could have done under the Directive 95/46/CE (Taylor & Smith, 2017, p.14).

Preliminary audit and the Data Protection Impact Assessment

As previously mentioned, the first step in complying with the GDPR should be conducting a thorough and sincere evaluation of current internal policies and procedures. Nevertheless, the manner in which the audit is to be conducted is dependant upon the existence or lack of prior procedures, aimed at respecting the obligations imposed by the Directive 95/46/CE. When such procedures already exist the focus should be placed on adapting them to the higher exigencies of the Regulation. If the

controller was not sufficiently diligent to create such procedures the task will be significantly more laborious. The preliminary audit should either be externalized or conducted by a current employee with expertise in data protection. Ideally, the audit should be externalized, as it would contribute to the objectivity of the results, given that a purely internal assessment could be subject to pressure from managers or other employees responsible for data protection to hide previous breaches or avoid findings that could only be resolved by means of costly investments.

The first objective of the preliminary audit should be to determine what data is currently being processed. This is necessary in order to verify whether the company has the obligation of naming a Data Protection Officer. Appointing a DPO is mandatory in three situations; namely when: (i) processing is carried out by a public authority or body, with the exception of courts acting in their judicial role; (ii) the principal activities of the controller or of the person in charge of the controller consist of processing operations which, by their nature, scope and/or purposes, require regular and systematic monitoring of the large-scale targeted persons; or (iii) the main activities of the controller or the processor by the controller consist scale processing of special categories of data referred to in Articles 9 and 10. Nevertheless, when a company will voluntarily choose to name a DPO, although the conditions for mandatory appointment are not fulfilled, Art 37-39 of the Regulation are fully applicable to said controller (Article 29 Working Party, p.5).

Although the notions of main activity, large scale and periodic and systematic monitoring are not clearly defined by the Regulation, several criteria can be used to understand their scope. The main activity encompasses operations necessary to achieve the social or lucrative purpose of the controller or processor. It also includes the case where data processing is logically interlinked to the nature of the controller's business (Article 29 Working Party, p.7). The notion of large scale, however, remains volatile enough to not be explicitly defined. Whether processing is large scale will be determined on a case by case basis, taking into consideration (i) the nature of processed data; (ii) the reasons for processing the data and (iii) what types of data subjects are affected by the processing, where aspects such as geographical, social and gender distribution should be addressed.

Finally, monitoring is periodic when it is continuous for certain periods of time or repeated at specified and systematic intervals when organized, follows a specific method, is part of a data or strategic data collection program. In addition to profiling, which is mentioned expressly in the statement of reasons, determining location by applications, health status through devices or telecommunications services are forms of monitoring.

After this initial assessment, the company should appoint a Data Protection Officer, either to fulfill its mandatory legal obligation or if this is the strategy for data protection adopted by the management of the company. However, the aforementioned rule, namely that appointing a Data Protection Officer when it is not mandatory will result in being held liable to the same standards as any company that must fulfill such an obligation, should be taken into consideration when making such a decision. If the processing falls under the scope of protection enshrined by Art. 37- 39 of the Regulation, the audit should continue only after a person in higher management is appointed to supervise personal data protection.

The preliminary audit should also establish how much data is currently stored or otherwise used by the company. This should include reference to any form of processing, including profiling of users. Next, steps should be taken towards data minimization. We consider that data should be classified in three categories: (i) necessary data, which includes data that is essential for the functioning of the company (e.g. a hospital cannot function without processing patients' medical records); (ii) useful data, which includes information that can aid the company in growing and expanding its activity (e.g. user data collected from the company's Facebook page, which includes the age groups of average visitors of the page, can be used as an important tool in targeted advertising) and (iii) unnecessary data. When data is unnecessary it should either be deleted, when possible, according to the rules imposed by the Regulation or it can be anonymized or pseudoanonymized (von dem Bussche Freiherr, Zeiter, 2016, p.577). Nevertheless, it should be established whether the data that is processed stems from vulnerable categories of data subjects, such as minors.

Once aspects concerning the nature of the data have been settled, the audit should focus on the current manner in which data is stored. The auditor should verify what parts of the data are physically stored and how much is digitally stored. It should be verified if there are current mechanisms in place to protect said data. Each type of data should have specific methods of protection. While installing CCTV cameras is a decent method for protecting data stored on physical mediums, digital data must also be secured against cyber-attacks. The operator should make sure to verify how data was collected and if (and how) the consent for processing the data was taken. The Regulation also applies to consent that has already been obtained, which means that the controller must ensure that consent for processing which was legally obtained at the time, but doesn't fulfill the current exigencies, set forth by the Regulation, is renewed.

The audit should also establish who has access to personal data in the company and for what purpose must they use the data. Most probably, the Human Resources department will use data for different purposes than the IT department. It should also be verified who was responsible for data protection before creating new procedures. Moreover, the audit should clearly show what data is distributed to third parties or data processors.

Finally, a Data Protection Impact Assessment (DPIA) must be conducted. Although some scholars argued that it is a mere compliance check (Wright & De Hert, 2012, p.34), it has been defined as *an instrument for eliminating or mitigating privacy and personal data risks which recognizes what data is being or is going to be processed in the future and justifies that processing; identifies, analyses and classifies the risks for natural persons; identifies and implements remedies to these risks; produces a report about the DPIA and monitors the processing for compliance with the DPIA and/or changes in the risks* (Yordanov, 2017, p.487). It is mandatory, according to Art. 35 of the Regulation, when a type of processing is likely to result in a high risk to the rights and freedoms of natural persons. Such an Assessment must include, at minimum: (i) a systematic description of the envisaged processing operations and the purposes of the processing, including, where applicable, the legitimate interest pursued by the controller; (ii) an assessment of the necessity and proportionality of the processing operations in relation to the purposes; (iii) an assessment of the risks to the rights and freedoms of data subjects referred to in paragraph and (iv) the measures envisaged to address the risks, including safeguards, security measures and mechanisms to ensure the protection of personal

data and to demonstrate compliance with this Regulation taking into account the rights and legitimate interests of data subjects and other persons concerned.

It has been shown that the concept of *high-risk* processing is a difficult and ambiguous one, and can differ from region to region, due to the cultural background (Voss, 2016, p.804). However, according to Article 29 Working Party, the main body for consultation and harmonization on all data protection matters within the EU, according to Paul De Hert and Vagelis Papakonstantinou (2016), several factors should be taken into consideration when assessing whether certain data processing imposes a high risk, which includes (Article 29 Working Party, pp.7-8): (i) Evaluation or scoring, including profiling and predicting, especially from “aspects concerning the data subject's performance at work, economic situation, health, personal preferences or interests, reliability or behavior, location or movements”; (ii) Automated-decision making with legal or similar significant effect. When the controller uses systematic methods that automatically assess data subjects' information there is a higher risk for misuse of data. The European legislator seems particularly distrustful concerning these types of practices, which will affect a large number of companies, especially in the field of Big Data (Zarsky, 2017, p.1017); (iii) Systematic monitoring since such processing can collect data that the subject is unaware of. This includes CCTV surveillance; (iv) whether data which is sensitive according to Art. 9 or stems from vulnerable data subjects is processed and (v) whether data is processed on a large scale; (v) Datasets that have been matched or combined; (vi) Innovative use or applying technological or organizational solutions and (vii) the processing in itself “prevents data subjects from exercising a right or using a service or a contract.

Putting new internal procedures into place and adapting contracts

There are three essential phases in actually implementing the GDPR, once the preliminary audit is finished. These include undertaking remediation activities, implementing operational changes and transitioning to business as usual (Bowman & Gufflet, 2017, p.261). The whole process is dependant upon creating clear internal rules for employees to follow. These procedures should be transparent and accessible to data subjects, also. According to Temme (2017) transparency is a fundamental pillar of the GDPR, and some activities, such as algorithmic decision making, can only be undertaken after ensuring that the *right to an explanation* is respected.

The procedures should, *de minimis*, address the following issues: **(i)** how data is stored, namely by establishing (a) what data will be stored on physical mediums; (b) what data will be only digitally stored; (c) clear rules as to the duration of data storage; (d) who will be responsible with checking the duration of data storage and deletion of data; (e) if any approvals are necessary in order to access the data and (f) procedures for tracking of data and its use; **(ii)** how the data will be protected, from both internal threats, such as employee-led data breaches or external attacks, especially cyber-attacks; **(iii)** how the rights of the data subject will be respected. For each of the rights enshrined by Art. 12-22 of the Regulation, a distinct procedure, which should include rather strict deadlines, should be established. These should include, (a) a procedure to provide information to the data subject, concerning how his data is used and the purpose for using it. Distinct procedures should be designed for data that was not obtained from the data subject; (b) a right to access procedure, which could be similar to the aforementioned one, since, it also entails providing information. This should include the

manner in which information is transmitted to the data subject (*e.g.* via e-mail, personal account on the company's site etc.); (c) a rectification procedure; (d) an erasure procedure; (e) a procedure to ensure that the data subject can restrict the processing of his data. The former three procedures should include clear rules for handling the requests from users and their route through different departments of the company.

Another important point is establishing an (f) portability procedure, which should establish which common and machine-readable format will be used by the controller, how the information given to the data subject will be extracted from company logs and rules concerning the secure transmission of information to other controllers. Moreover, a guideline for respecting the subject's right to object must be designed. It should include the manner in which objections are filled and information concerning decision making and communicating decisions concerning requests based on this right. Janal (2017) emphasizes that the Regulation does not provide a reasonability or proportionality in respecting portability.

Moreover, a central point of the regulation is notifying users of data breaches. As previously mentioned, as part of the preliminary audit, the problem of data breaches must be analyzed. The main purpose of this analysis is to establish the main causes of potential information leaks. Several distinct procedures should be established to accommodate the anticipated breaches. They should establish deadlines for notifying both the data subject and the national authority. Furthermore, a general procedure should be established, concerning other types of unanticipated problems concerning losing user information or fraudulent subtraction of said data. If the company also acts as a processor it must also notify the controller of the breach. When the data of a vulnerable person is processed, the competent authorities for supervision should also be notified. When data of a minor, for the processing of which parental consent is required, the controller must notify the parents or legal guardians (Esayas, 2014, p.352). Finally, the procedure should also contain subsequent measures for limiting the leaks.

Finally, internal sanctions should be established for potential failures of properly handling data and respecting the rights of the data subject. It is important that internal accountability exists and that the role of participants in processing data is defined, in order to ensure that any potential negligence can be attributed to a certain person or group.

Furthermore, clear procedures for requesting the consent of data subjects should be enacted. In this sense, employees who handle this issue should be instructed to adapt to the particular situation, by requesting consent based on the scope of the processing, when it is directly taken from the user. A registry for such information should exist and the procedure for transcription of information concerning the basis for each processing of data.

Conclusion

Although the GDPR imposes significant burdens on data controllers, with proper care, any low and medium tier controller can fulfill its obligations. As we have shown, the first steps in implementing the Regulation are the most important, as after putting the internal mechanism into place, the system should run *on autopilot*. As long as the purposes for processing and the potential risks are identified, the principles of

minimization and data protection by design are respected and clear internal procedures, adapted to the company's activities are adopted, complying with current standards is far from impossible.

Abstract. *The present undertaking aims to theoretically depict the opportunities and vulnerabilities that small and medium-sized enterprises (SMEs) are prone to face – unlike the bigger actors –, insisting on the internationalization conditions, from accessing relevant knowledge to deploying successful operations in foreign markets. The motivation to elaborate on this approach is determined by the fact that a better understanding of the SMEs cross-border performance in relation to their specific characteristics and inputs would provide additional insights into the future of small and medium-sized business and their topical ventures, especially in their foreign initiatives and projects. Further, a theoretical outlook on the existing opportunities and vulnerabilities would become an important step towards the formation of proper managerial attitudes and conducts regarding the organizational and environmental dynamics.*

Keywords: *small and medium-sized enterprises (SMEs); European Union; opportunity; vulnerability; internationalization.*

Introduction

Whether or not international actors (i.e., internationalizing or internationalized small and medium-sized enterprises) are causing severe changes nowadays in the worldwide business environment can no longer be minimized, thus putting forward a wide range of open questions. This reifies the rising importance of the European Union (EU) governments to act responsibly and proactively towards the small and medium-sized enterprises (SMEs), through favorable social and economic measures, meant to support them in the endeavor to thrive beyond borders.

SMEs propensity towards sustainable partnerships could be facilitated through an easier access to resources, through a pertinent knowledge and definition of their vulnerabilities, through a raised awareness about the benefits that the public and private sectors could extract from a timely adaptation (Pauw & Chan, 2018). This goes beyond sectors and types of institutions and engenders positive impacts at multiple

levels (Vătămănescu et al., 2014, 2016a, 2017; Vătămănescu, Alexandru & Andrei, 2015). The operative collaboration between different actors ranges from institutional channels to specialized social / business networks (Vătămănescu, Alexandru & Gorgos, 2014; Vătămănescu et al., 2015, 2016b, c, 2017; Vătămănescu & Alexandru, 2018; Vătămănescu et al., 2018). Here, the international experience of SMEs has highlighted the need to sustain weak SMEs by maintaining the policy focus on leaving behind non-lasting firms, while supporting viable firms (Bergthaler et al., 2015).

The extension of a business abroad helps SMEs have international operations with the aim to grow at the European level, inside and outside its borders (EC, 2018a). The internationalization of the SMEs is vital for the economic growth of the EU, for innovation as for competitiveness, as well as for accessing new markets and business-friendly environments. The internationalization has benefits for global value chains and the SMEs impact upon them, creating more jobs and diminishing delivery costs (EC, 2018b). In order to help SMEs internationalize, the EC has had policy dialogues, bilateral and multilateral, with the expectance of aligning the policy framework across European borders. In 2017, the workshop "8th EU-US-EU SME Best Practices Workshop in Wichita (USA)" was promoted by the EU to exchange expertise and to expand opportunities towards other markets. The percentage of the SMEs that export products or services is very small – around 26% in the EU and enterprises which export to other non-EU countries is even smaller (EC, 2018c). Via multifaceted instruments and mechanisms, the European Commission intends to aid enterprises to be prepared for competition, access foreign markets and develop businesses in non-European territories.

Progressively, the associated dynamics of SMEs internationalization sets itself up as an essential topic both in the political arena and research agenda of many scholars willing to properly depict the most relevant mechanisms and propelling factors towards successful internationalization. The companies which seek to engage in international entrepreneurial practices are steadily growing in number, while many existing companies are substantively shifting their focus from a local-based approach towards a global-centric outlook. It is hence critical to understand the state-of-the-art in terms of opportunities and constraints (vulnerabilities) featuring SMEs with a view to achieve a clear picture on the current phenomena. Moreover, nowadays, managers cannot limit themselves only to the present organizational issues and to the local demands. They are obliged to keep up with innovations in their area of interest, with the global trends in the market and with the development tendencies of their competitors, who activate internationally. In international enterprises, managers are trained in relation to the company's strategic aims through training programs in order to cement international competences (Vătămănescu, Alexandru & Gorgos, 2014; Vătămănescu, Alexandru & Andrei, 2015). In this line, globalization and internationalization are assumed through multidisciplinary solutions adopted by managers, taking into account the implications of managerial decisions in relation to outer organizational settings.

Corroborating the arguments above, the present study aims to theoretically explore the configuration of various opportunities and vulnerabilities which describe the SMEs trajectories in the process of internationalization. In this front, a literature review was conducted on the aforementioned key issues.

Gliding along the opportunities and vulnerabilities of SMEs: the international setting

At present, SMEs have become an important piece in the diagnosis of international relations; the desire to survive or to make progress derives from the exigence of the international conduct. The business environment has started to demand expeditious adaptive measurements in order to preserve competitiveness and sustainability (Hapenciuc et al., 2015; Păduraru et al., 2016; Soto-Acosta et al., 2016), to reduce costs and extend specialized markets (Cannon & Perreault, 1999; Vătămănescu et al., 2016c, 2017; Vătămănescu & Alexandru, 2018).

The global market plays an important role in the emergence and advance of business relations at the international level whereas it challenges enterprises to act adequately in the transnational arena. Looking at the extant literature review, it can be asserted that, due to today's broad array of incentives, the enterprises are somehow prone to approach and embrace internationalization (Cannon & Perreault, 1999; Harvie, 2008; Vătămănescu et al., 2014; Nicolescu & Nicolescu, 2016; Vătămănescu et al., 2017): the access to developed markets and to better resources; the advantages stemming from newly-explored markets; the reduction of production or distribution costs; the opportunity to follow competition; the avoidance of custom fees; international cooperation for obtaining competitive advantages, etc. Here, pursuant to Hilmeresson and Papaioannou (2015), the greater the international experience of SMEs, the more systematically they will search and harness international opportunities.

SMEs versus the bigger actors

Enterprises from developing countries learn from bigger actors, acquire knowledge and apply the learned perspectives to various sectors (Humphrey, 1995; Humphrey & Schmitz, 2002). Participating in global value chains provides opportunities for the SMEs to learn aspects of production, market access, and other specific activities (Navas-Aleman & Guerrero, 2016). Nonetheless, engaging in international networks is an incentive for fulfilling more services and acquiring new activities or partners.

These initiatives vary from an "opportunistic conduct" of the SMEs (Wyer & Smallbone, 1999) to the approach of Majocchi and Zuchella (2003), who insisted on the importance of a regardful analysis of the new market's specific conditions. Thereby, Majocchi and Zuchella (2003) assert that SMEs should not be perceived as big companies' clones. They should primarily focus on similar or proximate markets, which allow them to have a better understanding and an efficient management of familiar conditions. Nevertheless, the managers of SMEs have to carefully administer all types of activities so as to overcome the vulnerabilities produced by the lack of resources (Majocchi & Zuchella, 2003; Harvie, 2008): i. major costs of internationalization (e.g., personal costs, logistic, new locations fees and so on); ii. the exigence of a continuous professionalization (management as a profession, an actual science, not only the art to manage); iii. the need to control, choosing wisely the market (prior activities of research and understanding the market's distinctiveness); iv. policies and assets appliance (management has to show flexibility and adaptive capacity concerning marketing strategies, prices, advertising, and distribution); v. monitoring operational fluctuations (management has to monitor and evaluate international fluctuations in the first step of internationalization); vi.

management concerns (management has to detain the capacity to react to unexpected situations and to square up to potential risk in a dynamic manner).

The adaptive capacity is the ability of the system to change to new conditions brought by changing forces in the system (Wedawatta et al., 2011). While medium-sized firms try to adapt to new conditions and to leave behind non-profitable operations, internal reorganization and externalization, product differentiation, small firms are improving products and collaborations with entrepreneurs, networking, services in conditions of fewer resources (Giannacourou et al., 2015; Pauw & Chan, 2018). SMEs have flexibility of products and few points of access as specificities; concurrently fast reaction and pragmatic value assessment emerge as requirements (Kadlec & Mareš, 2003). Garagorri (2016) sustains that SMEs react faster than bigger companies and are more flexible, but most of them do not detain effective management systems and tools to maintain sustainability. Related to effective management, the concept of sustainable entrepreneurship derives from sustainable development and balances the social, economic and environmental objectives of the enterprise (Crals & Vereeck, 2005; Hapenciuc et al., 2015; Vătmănescu et al., 2016d). At this level, the lack of experience of the management team is a serious risk to the international focus and action, often resulting in its temptation to stay local, on domestic ground and not internationalize fast, laying emphasis on the perceived risk (Dimitratos et al., 2016). This latter vulnerability may also determine risks associated to economic and financial subsidence, depending on various factors (Bergthaler et al., 2015; Garagorri, 2016).

In many cases, SMEs strive to manage similar problems as those of bigger enterprises although they do not have the same resources. Hereto, Hampton and Rowell (2010, 2013) have analyzed the basis of small businesses internationalization, emphasizing that these have to deal with opportunities in a constant way and to solve risks in a competitive international business environment. In this line of argumentation, Senik et al. (2014, pp.35-36) propose a different approach of SMEs constraints, encountered especially in developing countries: 1. lack of resources (qualified human resources, competence and knowledge necessary for research and development of new markets, important instruments for gaining new clients); 2. financial constraints (the impossibility to acquire new technology, insufficient funds, the difficulty in obtaining loans and the long latency for receiving loans); 3. managers' attitudes (negative attitudes generated by potential risks, inherent and extrinsic incentives, lack of enthusiasm regarding new challenges, self-assurance in relation to actual facts); 4. enterprises' limited capacity (old products, less quality, old technology, the inexistence of research-development departments so as to innovate products and services); 5. political meddling (commercial barriers imposed by countries, non-incentive laws, hard standardizing industries); 6. managerial incompetence (the difficulty in gaining credibility, the lack of managerial abilities in an international context, human resources mobility, including managerial sector); 7. mental distance (cultural, linguistic, social and value-bond differences); 8. political differences (between the parent country and targeted countries, precarious information from the foreign authorities, major political change, bureaucracy); 9. parallel management of local and international operations (paradigm changes and thinking models adjustments, the need to gain information and knowledge, dynamic actions); 10. the competition with other enterprises (the requirement to innovate, to create products and competitive services, to position itself in relation to competition).

In this vein, Berghaler et al. (2015) posit that, in Western European countries, the greatest concerns of SMEs refer to high competition and the lack of customer demand while the least potential risks are corruption and malicious damage. Concurrently, the lack of customers has been reported as an important problem in the European Union's SMEs dynamics. For small enterprises, the second placed problem was reported to be the access to finance factor, while medium-sized enterprises reported difficulty in finding high quality labor force (including managers) and regarding competition (Karadag, 2016). As illustrated by Karadag (2016), small and medium-sized enterprises in the European Union are dealing with a test of survival, mainly due to credit conditions and the difficulties in finding skilled employees and new customers. The rules are usually established by the large customers: the contract details are determined by their position on the market and they prefer to order large quantities of products and organize promotions for their products (Vlajic, 2015). As Vlajic (2015) sustains, the customers' complaints are registered and claims are also specified to suppliers (e.g. delivered quantity less than ordered, delayed delivery, etc.). Therefore, the vulnerability comes from the imposed rules that affect directly the producer or the supplier, not the trader. For example, the purchasing behavior is currently determined by the lifestyle and media publicity about products which are bad for health, and for this reason, customers' preferences have become prior for managers' actions (Giannacourou, 2015). The programs of skills development have a secondary role in economic upgrading, with a greater role in revealing opportunities about social upgrading for the SMEs and their workers (Navas-Aleman & Guerrero, 2016).

Synthesizing the vulnerabilities of the SMEs, Le Ray (2006) describes three types of risks: financial (strategic, operational), need for resources (human, technological) and organizational approaches (environmental, management, projects). All these risks are determined by the level of debts, partnerships, and strategic orientation of the enterprise.

Towards an articulate outlook for SMEs internationalization

In the EU context, partnerships can increase the legitimacy of intervention for stakeholders by forming target groups which contribute to the implementation of projects in order to adapt to new conditions on the market (Pauw & Chan, 2018). Due to the small size of some businesses, the level of development of technological area might be costly for these enterprises (Vlajic, 2015) and remain unpractical.

Willing to depict the logic and the characteristics of SMEs cross-border processes, Senik et al. (2014, p.38) drew a descriptive outline which presents the main factors defining SMEs internationalization in emerging economies (see figure 1).

Generally speaking, SMEs also face obstacles when dealing with the global market even if international markets offer substantial opportunities. The interference with issues as compliance with foreign laws, mandatory rules of contract law, customs regulations, technical standards, and protecting intellectual or industrial property rights have a greater impact upon the companies' activities and services and claims for finding strategies to surpass them through a better understanding. When looking for external barriers, the most mentioned were: the lack of capital, inadequate information, and the lack of public support, difficulties with paper formalities, unknown laws, unexpected tariffs, and cultural differences (EC, 2014). The work of the SMEs with foreign partners

is sometimes hindered by not enough working capital; the difficulty of identifying foreign business and potential customers; not enough information to help them analyze markets; lack of managerial time (EC, 2014).

Figure 1. SMEs internationalization in Emerging Economies (Senik et al., 2014, p.38)

To overcome extant and potential inconveniences, the European Union has developed initiatives, including a policy platform under its Department on Enterprise and Industry, outlining a set of recommendations included in Small Business Act 2008. Resolving the problem of the SMEs loans in the European Union would cover a large spectrum of reforms for encouraging businesses to accelerate the process of restructuring (Bergthaler et al., 2015). In terms of governmental reforms, improvements in bureaucratic area were found to be effective and the facilitations for new registration were drivers of building new firms (Klapper & Love, 2011; Smallbone et al., 2013; Das & Das, 2014). The simple awareness concerning the existent facilities and risks of a certain business is a step towards finding elements that can surpass risks with a specific mode of operation (Saoudi & Foliard, 2017). Nevertheless, regulatory issues sometimes form obstacles because tax disincentives, debt forgiveness taxed as income may also be an obstacle, as well as overprotective labor rules might prevent meaningful restructuring. Governments may also face legal uncertainty to support debtors under EU state aid rules. Nevertheless, the European Commission recommendations have been given for enforcement settings in the EU that could be applied in all EU countries for obtaining a legal harmonization for the SMEs insolvency problems and for platform coordination (Bergthaler et al., 2015).

Conclusions

The evidence brought to the fore by the current study indicate that SMEs are faced with significant challenges in their various endeavors and, at the same time, that the European Commission has consistently acted towards supporting these businesses to grow and expand internationally via European initiatives meant to enforce their development. Several major European initiatives were described, laying emphasis on formal pathways accessible to SMEs.

Building on the specific needs and vulnerabilities encountered by the European SMEs, especially in terms of information and documentation, different specialized EU institutions have played an active role in offering easier access to relevant information regarding legislation and programs, financing options, the development of human capital, the improvement of management styles, the understanding of mental and environmental differences, of the prerequisites for innovation and competitiveness. By acquiring proper knowledge at these levels, SMEs would benefit from higher chances to adapt to new market conditions, to successfully enter foreign markets and thus be competitive. Acknowledging and further dealing with current vulnerabilities would provide SMEs with the capacity to manage businesses which are exposed to contextual factors liable to affect them to different extents. An adequate identification of the opportunities and vulnerabilities is a decisive factor for establishing SMEs performance in international settings.

Given the fact that the present paper mainly focused on the theoretical developments in the field, future studies revolving around relevant case studies would round off the general perspective. Correlating theory and facts would yield benefits for both the academic community and practitioners.

NEUROTECHNOLOGY WITH POTENTIAL FOR COGNITIVE ENHANCEMENT: INSIGHTS INTO BRAIN STIMULATION

Abstract. Brain neuromodulation techniques have been used extensively in neuroscience and cognitive psychology to alter the polarity of the brain resting membrane in order to influence behavior by applying mild current stimulation to targeted areas of the scalp correspondent to pathways in the brain responsible for particular functions. By these means, researchers have observed that cognitive performance, including attention, executive function, working memory and even language, could be enhanced or impaired according to the type of current applied to targeted area of the brain. Likewise, motor skills would be altered when the motor pathways were being targeted at the site of the stimulation. A number of studies have gone further to suggest that the effects elicited by this mild brain stimulation go beyond the time of the actual experiment and have the potential for long-lasting benefits in patients suffering from aphasia, depression, stress-related mental disorders, to name just a few. The positive results obtained by noninvasive brain stimulation are not limited however to mental health conditions, a growing literature has looked at how this intervention can be used in healthy participants to improve performance, reduce stress-related conditions or potentiate positive emotions. This paper is a review of one of these neuromodulatory techniques, transcranial direct current stimulation (tDCS) and its effects on cognitive performance, specifically face and object processing. In the absence of adverse effects and due to its relatively easy set-up, tDCS interventions have been used successfully in non-clinical protocols, becoming over the last two decades extremely popular outside the neuroscience laboratory, with private internet companies capitalizing on its success and making tDCS kits available for a wide spectrum of applications.

Keywords: neuromodulation; cognition; tDCS; noninvasive brain stimulation; face processing; object processing;

Introduction

In our daily interactions, object and face recognition are of crucial importance, allowing us to differentiate between individuals, decipher emotions in facial expressions, making sense of the world around us. Over the last decades, face processing has made the subject of numerous cognitive neuroscience and neuroimaging studies, looking at the biological underpinnings of these processes. Recent research has allowed for a deeper understanding of the subject matter by uncovering the cognitive and developmental mechanisms of object and face processing.

Surrounded by a multitude of visual stimuli, we recognize different classes of objects by combining their structural components, piecing the features together to identify an object in its entirety (Rivolta, 2016). The same process is true for faces, where by recognizing a component in isolation, the nose for example, can help identify the person it belongs to. Through evolution, we began to develop the capacity to perceive a face holistically, not merely as a sum of its components. The hypothesis that face processing involves a holistic approach, rather than parts-to-whole relationship, has been confirmed over time by researchers (Yin, 1969; Tanaka & Farah, 1993; Robbins & McKone, 2007; Le Grand et al., 2004).

During face recognition, the human visual system processes facial features, integrating them by gestalt principles, also known as holistic face processing. Behavioral studies paradigms like the composite effect and the part-whole effect have been providing evidence to support the holistic processing hypothesis. Composite effect refers to the ability to determine whether two identical top face halves are considered the same (McKone, 2008). The task becomes even more difficult, empirical evidence have shown, when the two identical top halves are paired with different bottom halves, suggesting that the whole-face context impacts of the recognition of facial features in one half of the face. The difficulty of recognizing familiar faces from isolated features has been referred to as the part-whole effect (Tanaka & Farah, 1993). The composite and part-whole effects suggest that features, rather than being recognized and processed independently, are seen holistically.

Human faces are multidimensional sources of information, with at least two levels of processing. A first one, relying on attributes found in every face, has a role in distinguishing between faces and objects. Research studies have shown that infants track face-like stimuli for longer times than non-face patterns (Farroni et al., 2005), while adults look firstly and for longer periods of time at face stimuli, than complex objects (Crouzet, Kirchner & Thorpe, 2010). All faces, supposedly, share the first-order information and to differentiate between them requires a second level of information relating to the variation existing between faces (Freire, Lee & Symons, 2000). There are three stages associated with face recognition (Maurer, 2002): detection, holistic processing and face discrimination.

Holistic processes can, however, be distinguished to a certain extent from second-order information when it comes to identifying familiar faces, compared to unfamiliar ones (Bruce et al., 1999; Megreya & Burton, 2006). When assessing familiar faces, changes in the viewpoint and expressions do not hinder accurate recognition but it does decrease the ability to recognize unfamiliar faces (Hancock, Bruce & Burton, 2000). Holistic processing, however, has been shown to influence the recognition of both familiar (Young, Hellawell & Hay, 1987) and unfamiliar faces (Le Grand et al., 2004), irrespective of viewpoint (McKone, 2008) or facial expression (Calder, Young, Keane & Dean, 2000). Moreover, research into contrast-reversed faces revealed that holistic processing is not impaired by contrast-reversal (Hole, George & Dunsmore, 1999) though it does disrupt individual recognition (Kemp, McManus & Piggot, 1990).

A study by Tsao and Livingstone (2008) looking at face perception has posited that holistic processing occurs prior to individual discrimination. In the case of inverted faces, a desensitization to second-order information takes place (Collishaw & Hole, 2000), impacting on the discrimination of inverted faces. Consequently, should holistic

processing have a role in extracting first-order information then a deterioration in detecting faces would also be registered.

Neural underlying structures of face processing

The special status of face processing has been the focus of research of cognitive neuroscientists interested in identifying the areas in the brain responsible for face processing. Technological developments such as functional magnetic resonance imaging (fMRI) have identified certain neural regions that respond strongly to faces, more than they do to objects, such as the Fusiform Face Area (FFA), localized within the human temporal lobe (Kanwisher et al., 1997). Future studies have confirmed the findings, proving that the FFA is the locus of holistic face processing (Liu et al., 2009; Yovel & Kanwisher, 2005).

The occipital face area (OFA), located in the occipital lobe, appears to have a role in the acknowledgement of facial features (Gauthier et al., 2000), the superior temporal sulcus (STS) in that of the dynamic of facial reactions and the anterior temporal face patch (ATFP), within the anterior temporal lobe, of facial identity (Gobbini & Haxby, 2007; Haxby et al., 2000). It is not solely by fMRI that the importance of these regions has been established, studies on the pathology of the neural face structures indicate that these play a causal role in face recognition (Dalrymple et al., 2011; Rossion, 2014) but not in other visual classes (Pitcher et al., 2011). Considerations in support of these findings are, on the one hand, that faces, more than other non-face stimuli, are identified at an individual level and, on the other hand, that humans are more experienced at recognizing faces (Gauthier & Tarr, 2002). Non-face objects however, generate an activation of face-selective brain regions when recognized at a subordinate level rather than a basic one. Moreover, increased recruitment of the FFA has been shown to be characteristic of expertise in non-face objects (Gauthier et al., 1997).

Most human beings are capable of easily recognizing hundreds of familiar faces. However, there is a very small proportion of the general population, about 2–3%, that has severe difficulties in recognizing familiar faces (Bowles et al., 2009). This impairment is known as congenital prosopagnosia (CP) (Behrmann & Avidan, 2005; Duchaine, 2000; Rivolta, Palermo, Schmalzl, & Coltheart, 2012). Individuals with CP, as opposed to the ones with acquired prosopagnosia (AP), who are not able to recognize faces as a result of a brain injury (Bodamer, 1947), never had the ability of recognizing faces (Avidan et al., 2011; Duchaine et al., 2007; Duchaine & Nakayama, 2005). Another characteristic of people suffering from CP is impairment in non-face object recognition (Behrmann et al., 2005; Dinkelacker et al., 2010; Duchaine et al., 2007).

Research into clinical cases like CP and AP have shown how essential being able to recognize faces and facial expressions is to social integration, enabling efficient communication and conformist behavior (Blair, 2003). Pathology of these functions has been observed in patients with schizophrenia (Kohler et al., 2003), psychopathy (Hastings et al., 2008), in the autism spectrum disorder (Law Smith et al., 2010) and with brain injury (Babbage et al., 2011). However, some of the great progress made in the study of prosopagnosia over the last decades has been characterized by a lack of general consensus in the results reported, that could be accounted for by the limited number of individuals with CP tested, the heterogeneity of cases, as well as by the different pattern of experimental tasks participants were requested to perform.

tDCS

Amongst the few interventions that have the potential to ameliorate the cognitive deficits associated with the symptoms in CP and AP is tDCS, a noninvasive technique involving a mild constant current stimulation (usually 1-2 mA) of the cerebral cortex by applying electrodes to the scalp surface. While anodal stimulation is believed to have excitatory effects on targeted brain regions, cathodal stimulation triggers inhibitory effects (Nitsche et al., 2003) due to a shift in membrane potential towards depolarization and hyper polarization respectively, similar to neuroplastic alterations of cortical function (Keeser et al., 2011; Kuo & Nitsche, 2012).

Though studies into the effects of anodal and cathodal stimulation on human behavior have been inconsistent, some of the results did show that anodal stimulation can enhance human cognitive abilities (Kuo & Nitsche, 2012; Barbieri et al., 2016) and when applied to the dorsolateral prefrontal cortex (DLPFC) it enhanced cognitive functions, including verbal skills, executive function and memory (Sparing et al., 2008; Dockery et al., 2009). Long-lasting benefits of tDCS were obtained over extended or multiple sessions, thus illustrating the potential for treating and improving cognitive deficits (Nitsche et al., 2009).

TDCS has a role in changing the excitability of the cortex resting membrane, resulting in depolarization or hyperpolarization respectively (Bindman et al., 1964; Creutzfeldt et al., 1962). A short session of tDCS can result in after-effects on the plasticity of the membrane that resemble long-term-potential (LTP) and long-term-depression (LTD) (Liebetanz et al., 2002; Nitsche et al., 2003), by altering calcium (Ca⁺) electrons, mediated by N-methyl-D-aspartate receptor (NMDA-R) (Barbieri et al., 2016). According to the literature, LTP is characteristic to cathodal electric stimulation, while LTD is typical to anodal stimulation (Fregni et al., 2015). Anodal tDCS (a-tDCS) has been shown to increase motor and cognitive skills in healthy participants, when stimulation was applied to the motor cortex (Nitsche et al., 2003) and the parietal cortex respectively (Roy et al., 2015). An enhanced performance of working memory has been achieved by applying a-tDCS to the dorso-lateral-prefrontal cortex (DLPFC) in healthy participants (Fregni et al., 2005), as well as in patients suffering from schizophrenia (Hoy et al., 2014; Shin et al., 2015), and reduced depressive states in chronic depression patients (Dell'Osso et al., 2012).

The positive results obtained with tDCS have generated great interest among researchers into the cognitive, neurological and clinical effects, with very few applications however to face processing, despite the great body of evidence provided by studies into cognitive (Bruce and Young, 1986), neural (Haxby et al., 2001) and clinical studies (Palermo et al., 2011), that suggest processing face stimuli is mediated by the same systems. A study that looked into the modulating effects of face processing in healthy controls applied transcranial Random Noise Stimulation (tRNS), a type of tCS in which the stimulation of low-intensity current is varied randomly (Terney et al., 2008), concluded that face perception skills are improved in individuals that received the stimulation (Romanska et al., 2015). Recent studies have shown that delivering a-tDCS over the orbito-frontal cortex (OFC) (Willis et al., 2015) enhances recognition of facial expressions in healthy controls. Research into the potential positive effects and various applications of tDCS, while laying the foundation by exploring some of the domains the

electrical stimulation can be used in, has left insufficiently explored areas. One of these areas is the contribution of a-tDCS in the recognition of face stimuli in a random population sample by modulating behaviors responsible for processing faces and objects.

Despite the progress made in the area of neuromodulation in general and its impact on face perception specifically, there are still theoretical and methodological aspects, as well as clinical, that can be explored. One such aspect would be looking for more evidence that the occipito-temporal lobe is specific to face processing rather than to other types of non-facial stimuli. While stimulating adjacent areas of the lateral occipital cortex by administering Transcranial Magnetic Stimulation (TMS) has resulted in impairments in the perception of faces, objects and other visual stimuli (Dilks et al., 2013; Pitcher et al., 2007), developing technologies that can result in an enhancement of visual perception for various categories of face and non-face stimuli is paramount.

Moreover, as memory has an important role in determining the performance of typical subjects in recognizing faces, determining if neuromodulation is not only impacting on face perception (Romanska et al., 2015), but also on the memory for faces, can reveal important insights into how the mechanisms of visual perception and memory are interconnected. On the basis of face-perception skills being circumscribed to a process that relies on the interpretation of facial features, with little contribution from the memory system, retaining and retrieving information on face identity is incumbent on face-memory performance (Dalrymple et al., 2014). The dissociation of these two processing systems in clinical subjects (Barton, 2008; Dalrymple et al., 2014), lends itself to further explorations into the enhancements brought about by tDCS.

An important factor to be taken into consideration when assessing task performance skills in tDCS experiments is the time the stimulation is applied in relation to task execution. Delivering a-tDCS to the motor cortex during a motor learning task has proved to be more effective than in the case of the stimulation occurring before the learning session (Kuo et al., 2008; Nitsche, et al., 2003; Stagg et al., 2011). However, delivering a-tDCS over the primary visual cortex before a discrimination task has generated stronger effects than when applied during task execution (Pirulli et al., 2013).

Though a-tDCS is believed to improve performance as opposed to c-tDCS, a recent study has shown (Constantino et al., 2017) that an inhibitory stimulation with c-tDCS does not always inhibit performance. The effects should be considered in relation to the timing and the application parameters that could alter the state of cortical networks carrying out a task. The application of a tDCS protocol that induces a depression in cortical activity over a specific stimulated area might result in increased sensitivity in visual performance. This is a further example of how the nervous system maintains a dynamic state to preserve performance in different environments.

Task performance was enhanced by c-tDCS when participants were administered the protocol prior to anodal stimulation as reported by studies into motor functions (Christova et al., 2015), while a 22 minutes with 1.5 mA over the occipital cortex improved performance in visual discrimination tasks (Pirulli et al., 2014), suggesting that the brain is regulating its activity, aiming to restore homeostasis following cortical depression as a result of c-tDCS. In this case the outcome is an enhanced excitability. Moreover, the effects of tDCS are much widespread than the area targeted by the

electrode, impacting adjacent cortical and subcortical networks at the same time (Bestmann et al. 2015), modulation of distant networks having been also reported by neuroimaging studies (Keeser et al., 2011).

Conclusions

Research into tDCS interventions are still inconclusive and though consensus has not been reached regarding its effectiveness, there is a great body of evidence suggesting that within certain parameters the protocol cannot only improve symptoms of clinical cases but has also been used successfully to elicit positive outcomes in healthy controls. These findings have great implications not only for future directions in neuroscience and cognitive psychology but also for organizations, where a slight increase in cognitive processes, be it attention, working memory or perception, for individuals performing high-risk decision roles, can make the difference between business as usual and an impasse that could affect economies or the security of thousands.

MATHEMATICAL MEASUREMENT OF THE CONCORDANCE BETWEEN PARTY DOCTRINE AND CANDIDATE SPEECH - A CREATIVE APPROACH TO ANALYZING POLITICAL DISCOURSE

Monica PĂTRUȚ

*Vasile Alecsandri University of Bacău
8 Spiru Haret St., Bacau, Romania
monicapatrut@yahoo.com*

Abstract. *This paper analyses the 2009 Romanian presidential election campaign, starting from the discursive conduct of the second round candidates, Traian Băsescu and Mircea Geoană. We have looked at the way in which the two candidates relate themselves to and/or promote the doctrines of their supporting parties: The Democratic Liberal Party and the Social Democratic Party. In order to outline the theoretical and methodological frame required by the analysis, we have suggested the term of accord to refer to the adequacy/correspondence between the party's program and that of the supported candidate. The accord will be described by using a mathematical model capable of representing the relations between the two categories of discourse. Approaching the accord between the party's program and that of the candidate was done from three perspectives: thematic, actional and axiological. Thematically speaking, we are interested in the extent to which the approached topics, the terms and the concepts by means of which the problems are identified in the discourse of the candidate are also found in the discourse of his party. In terms of action, we shall analyze the extent to which the same type of solutions to the same type of problems can be found in the two discourses. Axiologically speaking, we shall emphasize the common values promoted in the discourses of the candidates and political parties involved in the electoral race. We have resorted to content analysis to approach the candidates' discourses and the parties' political programs.*

Keywords: *political discourse; thematic accord; actional accord; axiological accord; political communication, Romania.*

From political doctrine to electoral platform: theoretical and methodological specifications

To approach the (dis)accord between the parties' political platforms and the candidates' election platforms, we have started from the finding that these convey themes or topics of national concern in an attempt to cover sectors or areas as wide as possible of the social reality. For the analysis, we have resorted to the following documents: *The governing political program of the Alliance Social Democratic Party + Conservative Party 2008- 2012*.¹⁰ *commitments to Romania* (www.psd.ro, December 2009), *The governing program of the Democratic Liberal Party (2009-2012)* (www.pdl.org.ro, December 2009), *Romania, one country – The political program of the candidate Mircea Geoană* (www.mirceageoana.ro, December 2009), *The political program of the candidate Traian Băsescu* (www.basescu.ro, December 2009).

As a research method for the discourses, we have used content analysis as it allows an objective, systematic and quantitative description of the manifest content of a communication. The method refers to the quantitative analysis of documents, aiming at

highlighting certain themes, tendencies, attitudes, values, patterns that are based upon a mechanism of converting a qualitatively symbolic material into a quantitative one. Therefore, we have separated the discourses into simple elements / themes in order to quantify, classify or hierarchize them. The quantitative analysis of these discourses will allow us to draw comparisons between the “communications” of parties and those of the candidates.

We have regarded objectivity and exactness as two characteristics that are compulsory for the analysis of documents and that is why we have used an encoding graph for the (sub)domains that the political/electoral programs refer to (Volken, 2005, pp.10-19). This graph consists of the set of the domains characteristic of the electoral/political discourses. In this set, we have included the following domains: 1) foreign policies, 2) freedom and democracy, 3) political system, 4) economy, 5) prosperity and life quality, 6) society structure and 7) social classes, groups and categories.

The seven domains are divided into 56 subdomains. Thus, the domain of Foreign policies is divided into: special foreign policies (positive or negative mentions), anti-imperialism, military (positive or negative mentions), peace, the European Community (positive or negative mentions), internationalism (positive or negative mentions). The domain Freedom and democracy consists of: freedom and human rights, democracy and the constitutional system (positive or negative mentions). The third domain includes the following subdomains: (de)centralization, governmental and administrative efficiency, political corruption and political authority. The fourth domain, Economy, contains: free initiative, market regulation, stimulation, economic planning, corporatism, protectionism, (positive or negative mentions), other economic goals, productivity, technology and infrastructure, controlled economy, nationalization, economic practice. The domain Prosperity and life quality comprises: environment protection, culture, social justice, extending social assistance, limiting social assistance, extending education, limiting education. The sixth domain, Society structure, is subdivided into: the national way of life (positive or negative mentions), traditional morality (positive or negative mentions), law and order, social harmony, multiculturalism (positive or negative mentions). The last domain covers the following subdomains: laboring groups and categories (positive or negative mentions), agriculture and farmers, the middle class and professional groups, underprivileged minority groups, demographic groups.

The encoding unit or the analyzed semantic unit from a political program is represented by the “*statement*” defined as an argument. In its shortest form, a statement contains a noun, a verb and an adjective, but political documents are rich in long statements that combine two or several arguments, usually separated by commas, semicolons or colons. The encoding starting point is represented by the statement, but what we are aiming at is, in fact, the argument (Volken, 2005, pp.27- 39). This is the expression of a political idea or a political aspect. We may use punctuation as a guiding principle in identifying arguments. Each argument must be placed in one of the seven domains, respectively subdomains that we have previously enumerated.

Political doctrine vs. electoral platform: doctrinal virtuality, discursive realization

We shall consider the political program of a party P as being a set of pairs of the form (T, S) , where T is a class of problems / themes (from a certain domain Dom), and S

represents the class of solutions by means of which these problems are solved. The party's program will be $P(P) = \{(T_1, S_1), (T_2, S_2), \dots (T_m, S_m)\}$.

A candidate C in the presidential elections is an element from the Party P , $C \in P$. For a candidate C we may define its program $P(C)$ as a set of couples (t, s) , where t represents a problem, and s a solution to it. The program of the candidate will be $P(C) = \{(t_1, s_1), (t_2, s_2), \dots, (t_n, s_n)\}$. For example, a candidate identifies, in his electoral discourse, the problem $t =$ "the citizen's relationship to the administration" for which he finds the solution $s =$ "restructuring, dismissals in the central or local administration".

The accord between the party's program and that of the candidate may be approached from three perspectives: thematic, actional and axiological. *Thematically* speaking, we are interested in the extent to which the approached topics, the terms and the concepts by means of which the problems are identified in the discourse of the candidate are also found in the discourse of his party. In terms of *action*, we shall analyze the extent to which the same type of solutions to the same type of problems can be found in the two discourses. *Axiologically* speaking, we shall emphasize the common values promoted in the discourses of the candidates and of the political parties involved in the electoral race.

A. The party's problems – the candidate's problems: thematic (dis)accord of programs

To measure the thematic accord between the discourse of a candidate and that of his party we shall take into account two mathematical relations that we shall compare with 50%. Thus, let us consider $n =$ the number of elements from the candidate's program $P(C)$ and $m =$ the number of elements from the party's program $P(P)$, as in (1):

$$n = |P(C)|, m = |P(P)| \quad (1)$$

If r is the number of problems of $P(C)$ that have a correspondent (by particularization) in classes of problems from $P(P)$, then the relation r/n represents the extent to which the themes from the doctrine of the party P can be found in the program of its candidate, and the relation r/m represents the extent to which the themes of the candidate can be found in those of the party.

If $r/n \geq 50\%$, then we shall say that there is a *P-thematic accord between the program of C and the program of P*, and if $r/m \geq 50\%$, then we shall say that there is a *C-thematic accord between the program of C and the program of P*. In other words, if at least half the themes approached by C in his program can be obtained by particularizations of the party's doctrine, then we are dealing with a *C-thematic accord*. On the other hand, when C approaches, in his electoral program, at least half the themes from the electoral program of the party that he represents (obviously, under a particularized form), then we are dealing with a *P-thematic accord* (Pătruț & Pătruț, 2010, pp.22- 24).

We shall note by *part_t* the thematic particularization function and we will be able to calculate the factor of thematic accord according to the formula below (2):

$$conc\_t(C,P) = |\{e = (t, s) \mid e \in P(C) \wedge \exists E = (T, S) \in P(P) : part\_t(T,t)\}| \quad (2)$$

Figure 1 contains a graphic representation of the notions previously presented, in a certain case.

Figure 1. The problem of thematic accord

B. The party's solutions – the candidate's solutions: actional (dis)accord of programs

In order to measure the actional accord between the discourse of a candidate and that of his party we may take into consideration two relations that we shall compare with 50%, just like in the case of the thematic accord. However, let us not forget that we cannot regard two elements $e \in P(C)$ and $E \in P(P)$ as being in actional accord unless they are already in thematic accord.

To measure the two types of actional accord of two discourses, one of a candidate C and the other of a party P , we shall use both the function of thematic particularization $part_t$, as well as a new function, that of actional particularization, that we shall note by $part_s$. If $part_t$ places into correspondence a general class of problems with a problem that is characteristic of the presidential election, $part_s$ performs a similar correspondence between a general class of solutions (a general method for solving certain problems) and a particular solution.

Thus, let us consider n =the number of elements (pairs of the type $(problem, solution)$) of $P(C)$ and m =the number of elements of $P(P)$. Let there r be the number of classes of problems of $P(P)$ that have a correspondent (by particularization) in problems from $P(C)$. As it has been shown, if $r/n \geq 50\%$, then we will say that there is a P -actional accord between C and P , and if $r/m \geq 50\%$, then we will say that there is a C -actional accord between C and P . It is possible that from the r problems of $P(P)$ that can be found in $P(C)$, part of them may be solved by the candidate differently from his party.

We will note $part_s$ the function of actional (solving) particularization and we will calculate the number of actional accord thus (3):

$$\text{conc}_s(C,P) = |\{e=(t,s); e \in P(C) \wedge \exists E=(T,S) \in P(P) : \text{part}_t(T,t) \wedge \text{part}_s(S,s)\}| \quad (3)$$

Therefore, between the discourse of the candidate and the discourse of his party, there is: *C*-actional accord, if $\text{conc}_s(C,P) / |P(C)| \geq 50\%$ and *P*-actional accord, if $\text{conc}_s(C,P) / |P(P)| \geq 50\%$ (Pătruț & Pătruț, 2010, pp.25- 26).

Figure 2. The problem of actional accord

In other words, if at least half the themes approached by *C* in his discourse have solutions that can be obtained by particularizations of the solutions of the party *P* to the same type of problems, then we are dealing with a *C*-actional accord. And when *C* approaches and solves at least half the themes from the party's electoral program in the manner suggested by the party, we say that we are dealing with a *P*-actional accord. Figure 2 is a graphic representation of the presented notions.

C. The party's values – the candidate's values: axiological (dis)accord of discourses

The political program reflects a party's or a candidate's reason of being at a given time or period. The program represents the synthesis of the political principles and values that are regarded as emblematic for that party or candidate. The political values found in the programs of political parties are those that have been established in time (freedom, equality, justice, personal initiative, ownership, lawfulness, constitutional state, tolerance, solidarity, responsibility) or that have been propelled into the present by various events or requirements (globalization, European integration, ecology).

In order to study the (dis)accord between the political programs of parties and the electoral program of the candidates supported by the respective parties, we have also

resorted to the identification of the political values conveyed by the two types of programs/discourses.

We have taken into consideration several terms that define political values and we have calculated their frequency of occurrence in the two electoral programs of the candidates, as well as in the political programs of the parties that supported the two candidates from the final of the presidential race.

We have paralleled the values promoted by each party with the values promoted by its candidate and thus we have identified three sets of values: values shared by the party and the candidate; values characteristic of the party and values characteristic of the candidate.

Just like in the case of the thematic or actional accord, we may calculate a *factor of axiological accord* by relating the number of common elements to the number of the elements from the two sets, that is, the number of values promoted by both sides as related to the number of values promoted by the party, respectively, by the candidate. Thus, we may speak about a *C-axiological accord* and about a *P-axiological accord* (Pătruț & Pătruț, 2010, pp.26- 27).

Case study: thematic, actional and axiological (dis)accord between the parties' programs and those of the candidates in the 2009 presidential elections

Taking into account the domains *Dom* that we have mentioned, analyzing the programs of the candidates of the SDP (Mircea Geoană) and of the DLP (Traian Băsescu) and comparing them both in terms of the problems, solutions and the values conveyed, we may identify the types of accord previously defined. In order to compare the problems and the solutions offered by the party and the candidate supported by it in the presidential elections, we have drawn, for each couple of candidate-party, a table as the one represented below, focusing upon the quantification of the thematic (TA) and actional (AA) accords between the programs (Pătruț, 2011, pp.45-50).

In this case: $\text{conc}_s(\text{candidate}, \text{party})$ is 5 and $\text{conc}_p(\text{candidate}, \text{party})$ is 3.

Thus, we were able to quantify the total of the themes in the programs of the parties and candidates involved in the final of the 2009 presidential race: $|P(MG)| = 29$, $|P(TB)| = 26$, $|P(SDP)| = 42$ and $|P(DLP)| = 49$. Then, we also calculated the accords between the parties and the candidates (see equations (4)-(7)).

$$\text{conc}_t(\text{"Mircea Geoană"}, \text{"SDP"}) = 23 \quad (4)$$

$$\text{conc}_s(\text{"Mircea Geoană"}, \text{"SDP"}) = 16 \quad (5)$$

$$\text{conc}_t(\text{"Traian Băsescu"}, \text{"DLP"}) = 25 \quad (6)$$

$$\text{conc}_s(\text{"Traian Băsescu"}, \text{"DLP"}) = 14 \quad (7)$$

We can see that in the case of both candidates there is a *C-thematic accord*: Mircea Geoană draws on 23 themes or problems out of the 42 suggested by his party ($54,76\% \geq 50\%$) and Traian Băsescu's program contains 25 themes taken from the 49 that the DLP raised ($51,02\% \geq 50\%$). In the case of both candidates, there is a consistent inclusion of the party's doctrinal elements in their own electoral programs.

Table 1. Model for calculating the thematic and actional accord

Dom	Problems raised by the party	Solutions offered by the party	Problems raised by the candidate	Solutions offered by the candidate	TA	AA
108	EU, NATO integration	Constitutional state, economic and political reforms, eliminating underdevelopment, national political consensus	EU integration	Adjusting domestic needs to the European model	✓	
202	Citizen involvement	Referenda/ ballot questions	Election involvement	Mobilization and education, making people aware of the importance of voting	✓	✓
303	Improving public authorities	Reform, applying the law	Taxes and contributions	Cuts and reorganization		
304	Corruption	Accurate laws, powerful institutions, authority of the law	Corruption	Independence of justice, reducing bureaucracy, authority of the law	✓	✓
501	Environment protection	Preserving the ecosystem	Environment protection	Extending green spaces, developing alternative energy sources	✓	✓
503	Decent standard of living	Equal access to education, health, housing	Decent standard of living	Cuts, assistance for the underprivileged categories	✓	

Similarly, for both candidates, there is a *P-thematic accord*: out of the 29 themes included in the electoral program by Mircea Geoană, 23 are shared by the party or are particularizations of those belonging to the party (79,31 %); in his electoral program, Traian Băsescu, too, allots a very large space to the themes taken or particularized from the DLP program: 96,15%, that is, 25 themes selected out of a total of 26 suggested themes. Practically, on the level of their own electoral programs, the candidates' inventiveness in terms of electoral themes is minimal, being replaced by a maximum conformation to the program suggested by the party.

According to the same calculus algorithm, we may calculate the total of the solutions suggested by the candidates and the parties supporting them: $|P(MG)| = 17$, $|P(TB)| = 16$, $|P(SDP)| = 19$ and $|P(DLP)| = 23$. Thus, we then find the existence of what we have defined by *C- actional accord* for both candidates: Mircea Geoană has taken or adjusted 16 solutions out of the 19 offered by the SDP ($84,21\% \geq 50\%$) and Traian Băsescu has taken or particularized 14 solutions out of the 21 offered by the DLP ($66,66\% \geq 50\%$). Similarly, there is also a *P-actional accord* in both cases since the candidates solve, to a large extent, the problems raised according to the way in which the party suggested

them to: 94,11% for Mircea Geoană (16 solutions taken from the program of the party out of the 17 proposed by the candidate) and 87,50 % for Traian Băsescu (14 solutions taken from the party's program out of the 16 suggested by himself).

Axiologically speaking, the program of the candidate Geoană conveys values characteristic of social democracy: market social economy, citizen social security, solidarity and social protection, citizen cooperation and dialogue, investment in education, research and the health sector, decentralization, professionalism and depolitization of local and central administration, the need to modernize the Romanian society, respect for the citizen, democracy and the constitutional state. Taking into account the interval of one year elapsed between the moment of designing the analyzed programs and the aggravation of the financial crisis in 2008-2009, the program of the SDP candidate pays increased attention to reforms, restructurings, planning and financial rationalization, work and social and individual responsibility, competitiveness and performance on all levels, efficiency, predictability and economic stability, optimism and hope for a better future, social dialogues among citizens or between citizens and government officials. An interesting fact is his appeal to the family and the community, to the cultural promotion of the country or to the protection of the environment. The values promoted by T. Băsescu in his program are largely taken from the program of his party and are inspired by the economic-financial crisis of Romania: modernization, society development or reform, democracy, constitutional state, social order and justice, tributariness and rural development, responsibility and involvement, love of the country and hope for its future, transparency, predictability and legislative stability, competence and entrepreneurial spirit, innovation, flexibility and constant learning, the need for solidarity, chance equality and cultural diversity. In the case of both candidates there is both a *C-axiological accord* and a *P-axiological accord* in terms of the values incorporated in their programs (Pătruț, Pătruț, & Cmeciu, 2014, pp.275-280).

Conclusions

Analyzing the accords between the parties' programs and those of the two finalists of the 2009 presidential elections we may wrongly conclude that the Romanian electoral debates mainly focus upon ideological problems and upon the analysis of the differences between the ideologies of the parties and/or candidates. We may also wrongly believe that the voters in our country own sound political knowledge and the majority votes according to the analyses applied to the political-ideological offers. In the national opinion polls that INSOMAR has carried out since 2004, 23% of the respondents do not know or do not answer when asked where they would place themselves on the right-left axis. From the respondents, the percentage of those regarded as ideologically competent is estimated to 25% at the most (Comșa, 2007, pp. 76-79). Moreover, the ideological elements taken by the candidates from their electoral programs and promoted in the public space during election campaigns are extremely few. Unfortunately, the candidates' interest in promoting the party's doctrine is actually done only theoretically, in brochures or on the Internet, and then is considerably diluted in (non)televised electoral debates. Probably, only the 25% of all the voters, those that are regarded as ideologically competent and that look for the data needed for the vote by themselves, benefit from this type of promotion.

BUSINESS ETHICS AND CSR

SUSTAINABILITY PERFORMANCE OF SMES: THE APPROACH TO NON-FINANCIAL REPORTING

Elena QUERCI

Insubria University

71Via Monte Generoso, Varese, Italy

elena.querchi@unisubria.it

Abstract. *In the immediate future, all companies will find themselves pursuing a balance between natural and social capital. Therefore, companies cannot exempt themselves from integrating environmental and social factors into their activities. It is no longer sufficient that only large companies, obliged by their own countries' legislation on EU guidelines, adapt to the presentation of non-financial reporting; SMEs must also start to highlight good practices in the area of sustainability. In fact, Directive 2014/95/EU suggests that companies not subject to the obligation submit a voluntary non-financial declaration on the areas indicated by providing simplified forms for SMEs. An exemption from the checks on the correctness of the non-financial statement is envisaged for such companies. In many cases, sustainability is inherent in SMEs, as they have a close link with the territory and the environment in which they operate, as well as with customers and suppliers. It is necessary to highlight their activities and to report them under the aspect of shared value with all stakeholders. Furthermore, SMEs can contribute to the SDGs 2030, as they are the backbone of national economies and the global supply chains of large companies. SMEs represent 99% of all companies, and if they have a limited environmental and social impact individually, they have a much larger impact as a group. The SDGs can be a strategic line of conduct to innovate products and create new business and at the same time bring out the most innovative and characterizing aspects of integration of sustainability by companies in connection with the 2030 sustainability objectives. With Key Performance Indicators (KPI) and sustainability performance, we can monitor the progress of the business process from both a quantitative and a qualitative point of view, thus discovering how an SME works in terms of accountability, sustainability and reporting back what is done to all stakeholders with legitimate interests. After an analysis of the literature to support integrating sustainability into SME business strategy, we will analyze two companies' approaches to sustainability through a case study of their different characteristics and choices in relation to the EU directive.*

Keywords: *SMEs; non-financial reporting; Key Performance Indicators; shared value; SDGs.*

Introduction

A company's participation within their local community influences SMEs' decisions to focus on socially responsible behavior, on the importance of social capital, and on all informal relationships with customers, suppliers and financial institutions. Although it is possible to identify CSR activities in PMI, the use of formal tools, such as codes, standards and social reports that testify to their existence, is not frequently observed (Vives, 2006). SMEs often sacrifice some of their profits to achieve a greater result, pursuing responsible behavior without any awareness. For this reason, we speak of sunken CSR or silent CSR (Perrini, 2006). Therefore, the smaller companies, although acting according to the principles of social responsibility, often fail to report and

communicate these behaviors to the outside world. Existing non-financial reporting tools for large companies are not immediately applicable to the reality of SMEs, for which KPI (Key Performance Indicators) have been studied and identified according to the GRI international reporting standard. These KPIs are suitable for measuring performance (PM) in SMEs (Santos et al., 2012).

It is necessary to drive SMEs to identify their activities in the following 5 sections considered essential for sustainable reporting:

1. economic performance
2. people and work relations
3. responsibility towards customers
4. environment
5. community and territory

As a business strategy, sustainable choices have become important to society and the business community. Sustainable development is seen as a promising paradigm through which natural capital, made up of natural resources and the environment, is preserved for future generations (Gazzola & Querci, 2017). In this way, a constant or increasing total capital (human capital plus natural capital) can be transmitted from generation to generation (Davies, 2013). The concept of sustainability involves all of the activities and decisions necessary to minimize environmental pollution caused by a company (Oberhofer & Dieplinger, 2014). The United Nations Brundtland Commission has defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their needs" (Brundtland, 1987). SMEs generally have a better understanding of the communities and the natural environment in which they operate than large companies. Close ties with customers, employees and suppliers and business integration with the life of the owners mean that integrating sustainability into their businesses can help them gain a competitive advantage in an ever-changing market. This advantage is attributable to their flexibility, smaller dimensions and limited number of employees.

Statement of a Problem

The EU Directive 95/2014/51 on non-financial reporting as an integral part of the financial statements of public companies and large companies provides for the possibility of SMEs to present a sustainability report. The penalties applied to large companies for non-compliance of the reporting are not applied to SMEs. This study developed a conceptual framework for evaluating SMEs' sustainability practices and their approach to non-financial reporting.

The three research questions taken into consideration are:

- the sustainability approach of SMEs
- the dissemination and specific characteristics of performance measurement (PM) in SMEs
- benchmarking activities through case studies

The case study presented here analyses two medium-sized enterprises that have close contact with the territory in which they operate, support environmental protection campaigns, and contribute to some of the UN's Sustainable Development Goals 2030. At the beginning of their activity, both companies adopted the low-cost, high-value philosophy and subsequently implemented the CRS in their business. Corporate

performance of these companies includes environmental and social aspects (Albertini, 2013). They are SMEs that have grown in turnover and commitment to the communities where they have operated for over a decade. They operate in light healthcare in Northern Italy: Santagostino Medical Center and Nau.

Organization and research method

After an analysis of the literature to support integrating sustainability in SME business strategy, we will analyze the approaches of these two companies. The work of Kathleen Eisenhard (1989) and R. K. Yin (1989) provides the guidelines for our case study, as they judged this the preferable form of research to determine “why and how” certain phenomena develop and evolve in specific contexts. Yin, in particular, described a case study as “*a research strategy, the distinguishing a characteristic of the case study is that it attempts to examine a contemporary phenomenon in its real-life context and especially when the boundaries between phenomenon and context are not clearly evident*”. *Experiments differ from this in that a phenomenon is deliberately isolated from its context. Histories differ in that they are limited to phenomena of the past, where relevant informants may be unavailable for interview and relevant events unavailable for direct observation.*” Moreover, Hartley (1994) states that research based on a case study “*is a detailed investigation, often with data collected over a period of time, of one more organizations, or groups within organizations, with a view to providing an analysis of the context and processes, involved in the phenomenon under study*”. Kaplan and Maxwell (1994) argued that the goal of understanding a phenomenon from the point of view of the participants and its particular social and institutional context is largely lost when textual data are quantified. Yin (1989) suggested applying the logic of “literal and theoretical replication”, which is based on the identification of cases that will give similar results (literal replication) or which will give different results, but for foreseeable reasons (theoretical replication). Through this working logic we can highlight the extension or the replication of the emerging theory. In our case, we have chosen “literal replication” by analyzing two types of SMEs to find similarities in their approaches to sustainability and the pursuit of a satisfactory economic result, as well as their contribution to some of the UN’s Sustainable Development Goals 2030.

Discussion

The contribution of SMEs to national economies is important. SMEs in the OECD area contribute to more than one third of the GDP in emerging economies and account for 34% and 52% of formal employment. On average they generate between 50% and 60% of value added (OECD, 2017b). SMEs are characterized by a naturally close daily relationship with customers, employees and suppliers, and they often integrate the business with family life. These close links facilitate their choice of sustainable activities. Among these characteristics, flexibility, rootedness in the territory and close relations with stakeholders, all of which encourage the integration of CSR activities, must be taken into consideration. It is necessary to identify the opportunities and the challenges that small- and medium-sized enterprises face when integrating CSR activities. The identification of sustainable strategies already adopted allows companies to develop awareness of the resources and skills already possessed, as well as those that are lacking, in order to adopt and implement actions and initiatives oriented toward CSR.

Above all, SMEs sustainability is identified through the processes they adopt, including cleaner production, waste-handling, eco-efficiency and logistics (Klewitz & Hansen,

2014). The level of incorporation of sustainability into SMEs' business strategies can differ; some choose a strong approach by committing to minimize or annul those environmental changes that produce irreversible losses, while others adopt a weaker approach to sustainability, presuming that future generations will be able to create enough wealth to cope with the negative consequences of their production activities (Davies 2013). More so than large companies, SMEs are subjected to external pressures to balance of the growth of human capital and natural capital (Tenuta, 2009). They can reach their goals through "sustainability-oriented innovation" (SOI) (Klewitz & Hansen, 2014).

Adams et al. (2016) define SOI as *"intentional changes to an organizations' philosophy and values, as well as must change its products, processes or practices to serve the specific purpose of creating and realizing social and environmental value in addition to economic returns"*. The authors also define the first level of SOI as "operational optimization", in which companies focus on "doing the same things better". They maintain consistency with changing regulations or pursuing efficiency gains, while they focus primarily on internal and incremental innovations. The innovation outcome is a reduction in the consumption of natural capital. During the second level, "organizational transformation", companies focus on "doing good by doing new things". They develop new products, services or business models, which may include a shift in the company's purpose. The innovation results in reducing harm and creating shared values with societal stakeholders. Finally, during the third level, called "systems building", companies focus on "doing good by doing things with others". In this stage, they start thinking beyond the firm and reconfigure the purpose of their business in society.

The rising societal pressures for responsible practices (increased transparency, community involvement, etc.) require the explication and dissemination of data derived from good practices. Article 14 of the Directive 2014/95/EU on disclosure of non-financial information provides for a request for disclosure of non-financial information for undertakings and groups other than large companies. Most of the member countries that have implemented all or part of the directive (figure 1) have provided for other companies not included in the range to be able to present financial reporting. In particular, this is already possible for Greek companies.

Greece has set mandatory limits for companies with the following limits:

- Over 10 employees
- Net turnover: over EUR 700,000;
- or Balance sheet total: over EUR 350,000

Directive 2014/95/EU complements and supports the achievement of the 2030 UN Goals compared to the SDGs, among others (Lenzi, Pais & Zucca, 2015):

8.2 Achieve higher levels of economic productivity through diversification, technological upgrading and innovation, including through a focus on high-value added and labor-intensive sectors.

8.3 Promote development-oriented policies that support productive activities, decent job creation, entrepreneurship, creativity and innovation, and encourage the formalization and growth of micro-, small- and medium-sized enterprises, including through access to financial services.

12.4 By 2020, achieve the environmentally sound management of chemicals and all wastes throughout their life cycle, in accordance with agreed international frameworks, and significantly reduce their release to air, water

and soil in order to minimize their adverse impacts on human health and the environment.

12.6: Encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle.

Figure 1. Member State Implementation of disclosure of non-financial information based on Directive 2014/95/EU (GRI & CSR Europe 2017, p.10)

The GRI standards (Global Reporting Initiative 2016) enable organizations to measure and understand their most critical impacts on the environment, society and the economy compared to the dimensions of sustainability. Economic concerns include an organization's impact on the economic conditions of its stakeholders and the effects on economic systems at local, national and global levels. Environmental concerns include an organization's impact on living and non-living natural systems, including land, air,

water and ecosystems. Social concerns include an organization's impact on the social systems within which it operates. The adoption of GRI standards means relying on the comparability of results at inter-company and inter-sectoral levels through the definition of a common framework that is recognized at a global level.

The topic-specific standards defined by the GRI are summarized in table 1.

Table 1. GRI topic-specific standards (Global Reporting Initiative 2016)

Economic Dimension	Environmental Dimension	Social Dimension	
Economic Performance	Materials	Employment	Rights of Indigenous Peoples
Market Presence	Energy	Labor/Management Relations	Human Rights Assessment
Indirect Economic Impacts	Water	Occupational Health and Safety	Local Communities
Procurement Practices	Biodiversity	Training and Education	Supplier Social Assessment
Anti-corruption	Emissions	Diversity and Equal Opportunity	Public Policy
Anti-competitive Behavior	Effluents and Waste	Non-discrimination	Customer Health and Safety
	Environmental Compliance	Freedom of Association and Collective Bargaining	Marketing and Labelling
	Supplier Environmental Assessment	Child Labor	Customer Privacy
		Forced or Compulsory Labor	Socioeconomic Compliance
		Security Practices	

Key Performance Indicators (KPIs) are indexes used to monitor the progress of certain business processes based on the triple bottom (Elkington, 1997) line of sustainability for measuring sustainability performance of companies. Since the company is not only financial and economic, but also social and environmental, it must report its results in each of the related areas. To measure the overall business result, the economic, environmental and social levels should be assessed, assigning the same weight to each area (Gray, 2004). In terms of development strategies, KPIs are one of the main tools for assessing the efficiency of production, elaborating based on this assessment and monitoring and controlling employees' business activities structural units and of enterprise as a whole (Lee et al., 2011).

The following are criteria for selecting indicator sets:

- 1) Ease and Understanding. KPIs must be chosen in such a way that there are no wrong or tendentious interpretations.
- 2) Significance. The function of the KPIs should be as a guide for decision-making in order to improve performance.
- 3) Comprehensiveness. The selection of KPIs must offer a significantly measurement of all of the activities and impacts across the economic, environmental and social areas.
- 4) Manageability and Comparability. Standardized KPIs must be chosen to make a benchmark activity of indicator results possible.

- 5) Controllability. Management must be able to vary the indicators by implementing corrective measures over time as stakeholders observe improvements.
- 6) Continuity. The chosen KPIs must be monitored and updated over time to observe the trends.
- 7) Efficiency. The cost of researching the indicators and monitoring them should not be particularly burdensome and complex in order to avoid compromising the performance itself (Baglieri & Vitaliano, 2014).

KPI guidelines can help SMEs cost-effectively manage and report their environmental performance. Some SMEs are not also effectively based on EU guidelines, others, or for the type of products / services or for being micro-enterprises, have an environmental impact as low as to be irrelevant. The effects on SMEs can be positive. SMEs can benefit from improving, and reporting on their environmental performance, because they may have stakeholders who require responsible behavior.

Case study: Santagostino Medical Centre (SMC) and Nau!

The companies involved in the case study are the Santagostino Medical Centre (SMC) and Nau!. The first offers light healthcare at fair costs and with high levels of quality. The companies involved in the case study are the Santagostino Medical Centre (SMC) and Nau!. The first offers light healthcare at fair costs and with high levels of quality. The second is retail establishment that sells and produces eyeglasses and sunglasses; they have an internal recycling program to produce glasses frames. Both companies have adopted the code of ethics suggested by the Assolwcost (Cinosi & Rizzo, 2013); subsequently, they have continued to follow this path.

They have strong ties with the community in which they operate, and they are committed to protecting the environment. Their communication of ethical and sustainable choices of production are more or less formalized. Santagostino Medical Centre publishes an annual report (Querci & Gazzola, 2017). The public activities and participation in the activities of the community where Nau! operates shows their commitment to the protection of the environment and the support of sporting activities. Therefore, both are SMEs that have not yet adhered to the voluntary possibility of non-financial reporting as foreseen by Directive 2014/95/UE, but they have all of the elements to be able to formalize their results through the KPIs and proceed with a benchmarking of their activities.

Table 2. Disclosure of Social Responsibility Santagostino Medical Center (Annual report 2017 Santagostino Medical Centre www.cmsantagostino.it)

SOCIAL RESPONSIBILITY SANTAGOSTINO GREEN
90% of the electricity consumption of our centers is derived from renewable sources.
LISTEN ONLUS: A GIFT THAT CARES
The patients of Santagostino (but not only) can donate visits and free medical care for people in economic and social difficulties reported by local associations. Fundraising is organized by the Ascolto Onlus.
Funds collected to date: about 11 thousand; euroPatients under treatment: 60
I GIVE
Also in 2017, in collaboration with Avis Comunale di Milano, we organized a blood collection campaign between May and June.

PARTNERSHIP WITH MUNICIPALITIES BUCCINASCO

The new Santagostino Medical Center of Buccinasco is the result of an important public-private partnership: the spaces are owned by the Municipality and for its management, the Santagostino has won a public tender. The presence of the Clinic fills a gap, left by the previous manager, responding to a need for territorial health.

SESTO SAN GIOVANNI

Also in 2017, Centro Medico Santagostino joined the project "Bene Comune grows with care" of the Municipality of Sesto San Giovanni. We have organized 4 workshops for children in the redeveloped square.

Since 2007, Nau! has sponsored the green ship of Legambiente (association involved in the protection of the sea and the natural environment). Nau! signature and supports projects for the defense and preservation of the environment, as well as campaigns to protect the ecosystem. For every pair of eyeglasses sold in recycled plastic, Nau! Makes a contribution to Legambiente (Querci, 2015).

The company made the first eyeglasses and sunglasses in recycled plastic. This pre-consumer recycling, takes place using the milling and curls of the frame machining. The scraps are recovered and reground in order to be reused as raw material for a new production of frames. Nau! uses renewable energy sources in their stores and biocartene shopping bags that can be reused by the customer for wet waste disposal. Their shops have eliminated the unnecessary packaging for liquids and contact lenses. Both companies pursue the right balance between sustainability and income results. The SMC turnover, from the 2009 to 2017, has grown respectively by 631.348 euros to 23.256.800 euros. Santagostino Medical Center's business model was replicated 14 times, leading to the opening of 14 new medical centers. In 2017, Nau! reached 135 single-brand stores, including direct stores (76) and franchises (59), and the closed 2017 with a turnover of 35 million euros, up 16% compared to 30 million the previous year. The year was marked by the opening of 22 stores, 18 of which were in Italy and 4 were abroad.

Conclusions

SMEs have a responsibility for their environmental impact on the environment. This responsibility puts constraints on their production and choices, while, at the same time, they must also comply with economic and legal constraints (Wickham 2004), all the time pursuing the right balance between natural and social capital. Those who choose to implement these social and environmental policies can obtain satisfactory profitability and increase the intangible value of consensus and reputation.

Although many companies take a silent approach to sustainability, it is necessary for good practices to emerge. Both individual national institutions and the EU encourage SMEs to make their sustainable strategies explicit. The EU Non-Financial Reporting Directive opens spaces for SMEs to share their KPIs publically. SMEs can reap positive benefits from measuring their indicators and transmitting their non-financial information. SMEs can benefit from improving and reporting on their environmental performance to stakeholders such as customers, neighbors and lenders who require responsible behavior. Both Santagostino Medical Center and Nau! are ethical, respect the environment and participate actively in the life of the communities where they operate. The business model of the Santagostino Medical Center has been carefully studied and evaluated by Databank to ascertain that lower prices are practiced thanks to the efficiency and quality of production and business organization and in compliance with

ethical values, social responsibility and respect for the environment. Confirming that sustainability is good for income growth, the Financial Times in 2018 lists the Santagostino Medical Center among the 1000 companies that grew the most in Europe. For the second consecutive year, Santagostino enters the annual report on the "FT 1000 - Europe's Fastest Growing Companies", which lists the companies of 31 European countries that have achieved the highest compound annual growth rate between 2013 and 2016. The growth rate of Santagostino between 2013 and 2016 was, as reported in the report, 209%. The compound annual growth rate (Cagr) in the same period was 45.6%.

On their website, Nau! declares, "in everything we offer we put passion, competence, respect for the environment and eco-sustainability. We are aware, always and not for fashion, of our responsibility towards the generations who will come and work together with our customers for sustainable development. In all our processes we eliminate what is superfluous and recycle everything that can be recycled. The result is clear: less waste for the environment and less unnecessary costs for you.

Abstract. *Benefit Corporation could be one of the possible reactions to having a new model of capitalism and business management because there is a combination of economic activities with the common satisfaction of social needs. In 2016, the Italian legal system introduces the case of the Benefit Company. Italy becomes the first state to acquire a discipline in this area of for-benefit companies, the analysis of the discipline configures the Benefit Companies as a context solution that mutates, as far as possible, the discipline of Benefit Corporation. The Italian Benefit Society is seen as a revolutionary step forward, in a traditionally static and sometimes obsolete context and the new law has generated a strong interest and enthusiasm and many companies have already decided to become a Benefit Company. The following paper is intended to illustrate the process that led to the birth of the B Corp movement and its first evolution in the United States with the legal legitimacy of the Benefit Corporation and then in Italy with the discipline of the Benefit Company. The objective is to verify the responses of the Italian context to the new legislation on Benefit Company, with particular reference to three aspects: 1. If the Benefit Company will be able to become an appropriate vehicle for entrepreneurs who want to operate in a sustainable way; 2. If the Benefit Company will be able to represent an interesting business model for those long-term investors looking for companies able to simultaneously generate economic and social benefits; 3. If the Italian experience will be able to produce a "domino effect" among other EU Member States that facilitate the dissemination of the "B" approach and, consequently, promote the establishment of companies with a strong positive impact measured with standard verifiable on social and environmental performance.*

Keywords: *Benefit Corporation; Business law; Corporate social responsibility; B Lab; Certified B Corporations.*

Introduction

The Benefit Corporation seems to be one of the possible answers to the need to reinvent a model of capitalism and business management that can combine a typical economic activity with the satisfaction of social needs. This kind of corporation was born legally in 2010 in the State of Maryland, but the basis of this phenomenon in the economic-business, are placed in 2006. In that year, the non-profit organization called B LAB was the promoter of this revolution. In 2007 B LAB certifies the first B(enefit) Corp(oration) applying the first version of the certification process called Benefit Impact Assessment (BIA). This is a process that proposes a system of evaluation of companies not only focusing the attention on the economic elements but also to the effects generated by the same business activity in the social and environmental field, with a particular attention to the definition of the Benefit and Impact concepts.

The certification process (B.I.A.) is divided into phases (Castellani, De Rossi & Rampa, 2016; Michellini et al., 2016; Lanza, 2017):

- First Phase. Self-assessment of the company where there is a spontaneous questionnaire to compile and subsequently it is required the transmission of documents to support the truthfulness of the information provided.
- Second phase: The company is required to demonstrate, through a "legal requirement", the ability to maintain sustainability criteria for a predefined period. Essentially it is required to demonstrate that a possible future management will have the real possibility of continuing to manage the business with sustainable criteria.
- Third Phase. Subscription of a declaration of "interdependence": this is a sort of "declaration of intent" where the company intends to network with the other Benefit Corporation; This is a relevant philosophy step to create useful connections capable to create added value and therefore a competitive advantage for the Benefit Corporation system.

The paper will illustrate the process that led to the birth of the B Corp movement and its evolution in the United States and then in Italy with the discipline of the Benefit Companies. One of the innovative elements fully replicated in the United States and in Italy is that of the certification process: The Benefit Impact Assessment. The Benefit Companies in Italy are pioneers of a new way of doing business, we will analyze the strategic choices made, the positive factors and the management problems that can emerge in relation to this kind of society.

The birth of the Benefit Corporation

The Dodge judgments *v. Ford* (H20, 1919) and the most recent *eBay Domestic Holdings, Inc. v. Newmark* (H20, 2010) contributed, over time, to the legitimacy and consolidation, in the US context, of Shareholder Primacy Theory (Grossman, 2005). In this theory the strong idea is that the top management and management of for-profit companies must act, in the best possible way, to achieve the maximization of value in favor of shareholders: they cannot and must not detect other types of considerations.

The shareholder primacy rule was used by courts to solve a dispute between the different categories of shareholders and this norm has evolved into the modern policy to the minority shareholder oppression (Armour, Deakin & Konzelmann, 2003; Mansell,

2015). This doctrine is criticized because it is in contrast with corporate social responsibility and other legal obligations due to the fact that it focuses exclusively on maximizing shareholder profits (Gazzola & Mella, 2012; Gazzola & Colombo, 2015; Flammer, 2015; Godfrey, Merrill & Hansen, 2009; Stikeleather, 2017).

In this context is born B LAB and the three founding partners, Andrew Kassoy, Bart Houlahan and Jay Coen Gilbert, had an initial approach to develop a proposal of legislation that institutionalizes the Benefit Corporation model. This process should be able to overcome the Shareholder Primacy Theory implementing some instances of the Stakeholder theory with other of the most recent Shared Value Approach (the set of policies and operational practices that increase the competitiveness of a company and at the same time improve the economic and social networks within the communities in which it operates) (Cummings, 2012; Green, 2017; White, 2014).

The features of a Benefit Corporation

B LAB elaborates a Model Benefit Corporate Legislation (Esposito, 2012; Hiller, 2013) because a Benefit Corporation is configured as a special form of enterprise, available only for "for-profit companies", and it has three main characteristics:

- A broader purpose: the purpose of a Benefit Corporation surpasses the unique idea to maximize profit for Shareholders to incorporate the pursuit of a General Public Benefit into the business activity and to add one or more Specific Public Benefits. A General Public Benefit is defined as a positive material impact on the Company and on the Environment while a Specific Public Benefit can be represented by the income support for individuals and communities, job creation or environmental protection against polluting practices (Nicholas & Sacco, 2016). The impact generated must be measured by a "third-party standard" organism.
- Extended responsibility: the responsibilities of the management of a Benefit Corporation are extended. The directors must consider the impact of their choices not only on Shareholders but also on the Stakeholders (Reiser, 2011; Cummings, 2012).
- Transparency: The Benefit Corporation must publish an annual Benefit Report and an overall assessment that indicates the ways in which the Benefit Corporation has pursued the General Public Benefit and its degree of achievement (Robson, 2015).

Certified Benefit Corporation™

B LAB, in addition to developing a Model Benefit Corporation Legislation, implements a certification process, that is capable to evaluate an overall way the impact of the economic activity of companies as well as the corporate social performance and environmental sustainability of the same called Benefit Impact Assessment (BIA). The B.I.A. allows, by meeting the requirements, to certify a company as a Certified Benefit Corporation and it has a numerical score on a scale from 0 to 200 to measure the different characteristics of the firms (Rawhouser, Cummings & Crane, 2015).

The benefit impact assessment

As stated in the previous paragraph, B LAB, since its establishment in 2006, has developed its own certification process called Benefit Impact Assessment. The purpose of this method is to measure the social and environmental performance of a company and, at the end of the process, to release Certified Benefit Corporation™ certification. The certification is valid for two years and allows companies to boast a brand that, is acquiring an increasing importance also in relation to the B Corp Movement diffusion (of which B LAB is the natural reference).

What is the BIA (BIA, 2018)

The BIA is defined as a "free tool" that helps transform the idea of managing the company as a positive force in a series of concrete, measurable and achievable actions. It is the obligatory starting point to evaluate, compare and improve the social and environmental performance of the company without any costs (Nigri, Michelini & Grieco, 2017). The unique cost (that it is due if the company completes all the phases of the certification process obtaining the qualification of Certified Benefit Corporation) in favor of B Lab is represented to an annual fee that is related to the past year sales value.

There are the same phases that a firm must follow to complete this process (Dahlberg, 2016):

Figure 1 BIA Phases

Figure 2 BIA corporate organs (Clark Jr & Babson 2011; Honeymann, 2014)

The specificity of the BIA

The Benefit Impact Assessment has particular characteristics that have made it as one of the most complete and widespread standards of social and environmental impact assessment (at least in the United States of America).

Table 7. The specificity of the BIA (Nigri, Michelini, & Grieco, 2017; Clark Jr & Babson 2011; Honeymann, 2014; Moroz et al., 2018)

Elements	Description
Focus on Positive Impact	The actions that intentionally address the solution of real social and environmental problems are assessed and measured, not only to respect the disciplines and regulations law
All-encompassing and easy to use	All the activities carried out by the company (of any size) are measured and which concern workers, suppliers, the production process, the governance structure is considered
Educational	It allows entrepreneurs and business employees who approach the certification process to measure their level of social and environmental impact
Transparent	The evaluation and weighting criteria for each question of impact areas, sections and sub-categories are available in the assessment process

Elements	Description
Independent	The Standard Advisory Council governs the BIA and the quality of the standard itself. It is made up of entrepreneurs and academics who are experts in the specific fields of process analysis
Dynamic	The process is updated and/or developed every two years

The differences between B Corp and Benefit Corporation

The NGO B LAB, since its establishment, has seen its name closely linked to the B Corporation Movement: it has implemented a certification process (the Benefit Impact Assessment) that has taken on the characteristic of a Third-party standard (Honeyman, 2014). It has contributed to the definition of a Model Benefit Corporation Legislation which has become the necessary point of reference for the drafting of a legislative framework (Moroz et al., 2018; Wilburn & Wilburn, 2014) with a connection between the B Corp in a network constituting a real Community of companies that share the same ideas and ideals in terms of exercising the business activity with a relevant part in the social field. B LAB grants, at the end of the Benefit Impact Assessment process the Certified Benefit Corporation™ a certification mark. The Benefit Corporation is a legal institution that sets up a special business model and it is important to underline that the two entities have important points in common, but also specific and distinctive characteristics reassumed in the following table:

Table 8. Differences between B Corp and Benefit Corporation (Honeyman, 2014; Davis et al., 2012)

Elements	B Corp Certified	Benefit Corporation
Accountability	The directors must take into account the effects of their decisions on both shareholders and stakeholders	Equal to the B Corp Certified
Transparency	The company must make public a report that evaluates its overall impact, drawn up according to an independent standard	Equal to the B Corp Certified
Performance	The performances are verified and certified by the B Lab through the B Impact Assessment standard. A performance >= 80 points out of 200 must be demonstrated.	Self-declared
Permanent checks	It must renew the certification every two years	The only verification over time is related to transparency requirements
Assistance and use of the 'Certified B Corp®' Brand	Access to a range of services and support from B Lab. Certified B Corps can use the 'Certified B Corp' brand and	B Corp® brand cannot be used

Elements	B Corp Certified	Benefit Corporation
	logo on their products and in all their communications No formal support from B Lab.	
Use	Any private enterprise anywhere in the world	Only in the United States that have approved the law on Benefits

The diffusion of the Benefit Corporation in the United States of America

B LAB certifies the first 19 B Corp in 2007, more than 2,500 in the first semester of 2018 and more than 50 States that have at least one (Benefit Corporation & Società benefit). The B.I.A. governed by B LAB allows the NGO to coordinate the B Corp in a network of relationships and set up a real community of businesses, but the most important milestone is the legal recognition: in 2010 the State of Maryland is the first to promulgate a regulation on Benefit Corporation, today the regulation is present in 33 Federal States, while in 6 others the specific procedures of legislative approval are launched.

The diffusion of the B-Corporation in the world

The B Corp movement is spreading even outside the United States of America. It is not possible to identify a univocal trend on the reasons that push companies to share the requests proposed by B LAB, but it is often the intuition of the entrepreneur, in a broad sense, to push, usually in a first phase, to undergo the process to have a certification. One example is represented by the experience of the founders of Nativa.

Nativa is one of the founding companies of the movement in Europe, the first B Corp in Italy and an Italian partner of B Lab. It has collaborated with the Senate for the introduction of the Benefits Society law, moreover, it is committed to promoting the movement and accompanies the companies involved along the path of evaluating their positive impact. For the management of this society, this situation became a stimulus to act: "The fifth time we got the approval (of the Chamber of Commerce of Milan), even if it actually constituted a" forcing "not provided for by Italian law. An article in Corriere defined us this way: "Nativa, the company that produces happiness". But the pioneering flag was not enough for us. For this reason, we have committed ourselves to get out of this illegality and create the conditions for the dominant model of the company to be guided by a common benefit purpose (for this reason) we have promoted the creation of the legal form of Benefit Company in Italy " (Natalab, 2015).

The governance and management distinctive elements of a B-Corporation in Italy (Bauco et al., 2017)

The corporate purpose

The Benefit Company must indicate, the specific purposes of common benefit that it intends to pursue and the aim that constitutes the social purpose. These objectives are followed by the management that should balance the interests of the shareholders and the interests of the stakeholders.

The management of Benefit Companies

In Italy, the Benefit Company will be managed according to the rules of the type of company adopted, appropriately declined according to the provisions of paragraph 380 of law no. 208/2015. The management of the Benefit Company must pursue further objectives (compared to those related to the correct pursuit of statutory obligations and legal obligations) coinciding with the balancing of the interests of the members. Moreover, the management must pursue common benefit objectives and the interests of people, communities, territories, and environment, cultural and social assets and activities and other stakeholders. Finally, the management of the company must necessarily take responsibility in a responsible, sustainable and transparent way to people, communities, territories and the environment, cultural and social assets and activities, bodies, and associations and other stakeholders, as well as the members.

The responsibility of the management

The Benefit Company, without prejudice to the provisions of the regulations for each type of company envisaged by the Italian Civil Code, identifies the subject or the persons in charge to whom assign functions and tasks aimed to pursue the aforementioned purposes.

The annual report for Benefit Companies

The detailed annual report has contents specified by the law:

- i) the description of the specific objectives, methods and actions implemented by the directors for the pursuit of the common benefit objectives and any circumstances that have prevented or slowed down the process (a forecast may represent an extenuating factor in the assessment of the unlawful conduct for not having pursued the purposes of benefit paragraph sanctionable by the AGCM);
- ii) the assessment of the impact generated using the external evaluation standard in accordance with the characteristics described in annex 4 of law no. 208/2015 and which includes the assessment areas identified in Annex 5 of the same law;
- iii) a section dedicated to the description of the new objectives that the company intends to pursue in the following year.

The purpose of the report is disclosure of the administration activity specifically aimed at achieving the common benefit achieved during the year.

Advantages, disadvantages strength and weakness of a Benefit Company (André 2012; Boatright, 2006; Esposito, 2012; Honeyman, 2016; Lanza, 2017)

Below is a list of the possible positive and adverse effects that can be generated by becoming a B-Corp or being a Benefit corporation:

Positive Effects	Critical Elements	Features of the Italian Context
• Be part of a community • Attract Talents • Media and Brand attractiveness • More investment and Saving money • Driving the change in a long term mission and to be able to attract investors	• Not Clear when a B-Corp certified can take the legal form of Benefit Company • There is no Register of the "Annual Reports of the Common Beneficiary Activities" • It is not obligatory for companies to make public the name of the corporate entity appointed responsible for the of the Benefit Company	• The ability to attract Millennials • The redefinition of Management Responsibilities • Strengthening the rights of Shareholders and Investors • Attractiveness for retail investors

Figure 3. Negative and positive effects

Conclusions and limits of the Benefit Companies

One of the debates that are developing in the field of Economic Sciences is that which concerns the ultimate goal of companies and societies; topics such as Circular Economy, Shared Economy, Stakeholder Theory, Hybrid Societies are well known and variously argued. Benefit Corporation and Benefit Societies are fully part of this debate: for-profit companies which, in the exercise of an economic activity, broaden their scope to social and/or environmental objectives and this extended purpose is constitutive for the birth of society and necessary for its continuity/existence.

Figure 4. Number of B Firms in Italy

The analysis of the B Corp movement numbers can give rise to doubts: in 10 years of existence the B Corp certified worldwide are little more than 2000 and particularly concentrated in the United States where the movement has its roots; on the other hand, it is surprising that a movement "on the square" for 10 years and with growth rates that are certainly positive, but not surprising, manages to catalyze attention, both vital and capable of re-proposing even outside its natural channel.

The numbers in Italy are not yet significant, but some elements can be highlighted: There are companies that have become B Corp even before that, in Italy existed a legal discipline that qualified them.

Figure 5. Number of B Firms in Italy per geographic zone

Main evidence (ODIB, 2017; Sole24 ore, 2017)

As at 30 June 2017, the benefits companies registered in the business register were 110, so in six months they almost doubled compared to the analysis made at the end of 2016, where there were 64 companies. Therefore, there was an increase of almost 72%. Specifically:

- The regional distribution, however, still rewards the North significantly from 44 companies to 71 (+ 38%).
- However, we note a strong recovery in Central Italy, which effectively triples the presence of the benefits companies from 11 to 29 companies (+ 163%).
- Tail light, unfortunately, remains the South which, in fact, does not grow.

At the regional level, 40 companies are based in Lombardy (of which 28, so 70%, only in the city of Milan, and over half - 56% - of the total number of companies based in the North.). It follows, but rather distanced, the Lazio that at 30 June had 19 benefit societies.

- Almost 20% of Benefit Companies focus on information technology, usually in the field of web services and e-commerce. The following are personal care (health, social care, medical devices, and wellness), agri-food and environmental firms.
- In general, they are mainly small companies (only 8 are S.p.A., while 90% are S.r.l.), with a strong approach to innovation and environmental protection.

Finally, it is important to underline that the adoption of the model of the Benefit Companies is still at an early stage: the normative discipline has the form of a frame within which the canvas still has many white areas. The main problems concern:

- The ability of the model to concretely guide the company in the direction of the plurality of objectives to be achieved.
- The mechanisms that will allow the Management to reconcile the potentially conflicting goals of profit and socio-environmental wellbeing.
- The sphere of new skills that managers will have to acquire for the exercise of their functions and for the definition of their new responsibilities and capacity for action.
- The evidence of the case in question suggests that the will to operate according to unconventional schemes and in respect of non-eminently economic sensitivities originates from the individual subject-entrepreneur, as a constitutive and essential element in the exercise of business activity and capable of positively influencing the subjects (stakeholders) who enter into a mutual relationship; an element that, however, needs a legal framework to be able to replicate in time and space.

Abstract. Many tourism destinations worldwide have lost their attractiveness and reached stagnation. In order to enable them to find a way to rejuvenate they need to find new innovative offers and explore new target markets. Recent changes in the population, in particular the aging factor, enable to identify new promising markets, such seniors. Seniors are considered as an important new target market to invest in since they have spending power to travel and they travel for longer time and off-season. Although seniors are an interesting market, they bring with them the effects of ageing, i.e., disability. Among different disability, dementia plays an important role. This made policy makers and businesses starting to be interested in dementia tourism. Some supply led initiatives have already been created, but further insights are needed to understand whether people with dementia and their caregivers are interested in such offers. This paper aims to explore this further. The qualitative findings of this research shows that people with dementia and their caregivers will benefit of such tourism offers, and they are willing to participate in them if extra-care is offered. This shades positive lights on the fact that such an offer could be successful. However, it is important to notice that not every caregiver is positive in making their beloved one participating in such activities, and they won't be willing to participate as well. As a matter of fact, factors such as the level of cognitive impairments, and the level of behavioral impairments influence the possibility to join such activities. The willingness of joining such activities is also influence by the family bond: husbands and wives are more prone to participate than children. This depends as well on the perception of tourism as a beneficial activity by caregivers, and the need of diversion, respite, and enjoyment of time together. If caregivers do not see tourism as something positive for their wellbeing and the one of the beloved one they will not be interested. Last but not least the lifestyle before dementia and past experience of tourism in early stage of dementia influence strongly the willingness to participate. With this in mind the markers should spend time in making sure

that this offer will be appealing to their target market before starting an initiative, which although being extremely good in theory, might not be actually needed in the reality.

Keywords: *destination rejuvenation; seniors; dementia friendly tourism; people with dementia; caregivers; enablers for dementia friendly tourism.*

Introduction

For many destinations living the challenge to find ways for rejuvenation, there is an urgent need to innovate their products and identify new targets for tourism development. For them an alternative positioning strategy is needed to deliver superior value to existing and alternative clients (Kotler, Bowen & Makens, 2014). One of the new markets on which to invest is seniors with dementia and their caregivers. The encounter between tourism and dementia creates a niche market that represents an opportunity for rejuvenation (Page, Innis & Cutler, 2014). As it is well known the World population is ageing (UN, 2014), and as a consequence, ageing diseases are as well increasing. Among different ageing disease, the most common one is dementia (60-70% of dementia is due to Alzheimer (WHO, 2012)). Due to dementia people see their cognitive ability deteriorate and their behavioral problems increase, compromising their emotional control, and social behavior (Mace & Robins, 2006). This causes as well caregivers' burnout (Alzheimer Research UK, 2015). In such a scenario it will be important to provide people with dementia and their caregivers, opportunities, among which tourism opportunities, that will allow them to remain active (Page et al., 2014).

Under this circumstance a tourism offer for people with dementia could benefit them and also stakeholders at tourism destination that see in it an important business opportunity (Page et al., 2014). Some governments have already recognized this opportunity and already invested in it (e.g., UK). One of researches on dementia tourism was the one of Page et al., (2014). They looked into the topic of dementia friendly tourism destinations by researching the supply side. Although this effort was extremely important, little has been done into looking at the demand side. The aim of this paper is to enable further understanding into this aspect. It explores the willingness of people with dementia and their caregivers to take part to tourism activities with the aim of giving to policy makers and entrepreneurs a clearer understanding of whether investing in dementia tourism could be convenient.

Literature review

The current tourism scenario is characterized by the existence of some tourism destination that lost their attractiveness as tourism destination due to different reasons. Under these circumstances these destinations are entrapped in the stagnation: they lost their attractiveness and are at a crossroad between finding ways for rejuvenation or abandoning the tourism industry (Baum, 1998). If these destinations are willing to find opportunities for rejuvenation it is needed, according to Faulkner (2002), to identify innovative products and new targets. This will then allow them to redefine its positioning strategy (Kotler et al., 2014) by identifying more appealing value propositions to new markets. Given the recent increase of them, one of the potential new markets explored are the seniors. This paper emphasizes on the likelihood of investing on seniors' tourism by looking on a particular sub-niche of the seniors: seniors with dementia.

Yeoman and Butterfield (2011) underline how nowadays the demographic changes, in particular ageing population, strongly influence the population characteristics, their behavior and preferences. They also create new and attractive trends for tourism development (e.g., senior tourists, and disable tourists). Senior tourism is a growing market (Paxson, 2009, Nimrod, 2008) that, as per WTO (2001) will characterize tourism development for the future. Seniors are seen as the future most important target for tourism destinations and organizations (Huang & Tsai, 2003, Fleischer & Pizam, 2002): if destination are able to grasp this opportunity, as long as the one of disable tourists, they will be able to develop a strong competitive advantage that creates value for a growing target (Alén, Losada & Domínguez, 2012) and themselves. Since seniors have high willingness to travel and holiday for long periods, also off-season (Fernandez-Morales & Mayorga-Toledano, 2008) this ensures a good level of tourism expenses in the destination that might enable destinations to prosper. According to Buhalis, Eichhorn, Michopoulou & Miller (2005) the value for accessible tourism, that includes seniors and disabled people (in 127.5 million of tourists in Europe), is high. It is estimated on average on 124.5 billion€ (Alén et al., 2012). According to Frye (2015) 2 out of 3 of disabled people are over pension age, and 1 out of 3 has some form of cognitive disability such as dementia. More and more seniors and disabled people would like to travel – travel is a fundamental right (Darcy & Buhalis, 2011) – it is important to set conditions to allow people with disabilities, among other dementia, to travel. The creation of universally designed tourism products is the key for this (Darcy & Dickson, 2009). This would also create a stronger connection between social welfare, community (Williams, Rattray & Grimes, 2006, Wu & Cheng, 2008), disabled people, and business outcomes (Sheldon & Tucker, 2005).

Since 2012 dementia has been recognized as a priority of public health (WHO). Every year 7.7 million new cases of dementia are diagnosed, and no cure exists (WHO, 2015). Dementia is defined as a disease of the central nervous system that bring to cognitive impairments due to progressive deterioration of the brain (Calvarese & Lovati, 2014; WHO, 2015). The first symptom associated with dementia is a memory loss, however there are other symptoms that cause the inability of people with dementia to continue living their lives normally. Dementia affects orientation, comprehension, language, and judgment, etc. (WHO, 2015). It is as well accompanied by behavioral symptoms (e.g., depression, anxiety, aggression, apathy, wandering, etc.) that affect people emotional control, and social behavior. Being dementia an increasing issue for many seniors (46.8 million people affected by dementia in 2015 world wide, with 74.7 million forecasted within 2030, and 131.5 million within 2050, and a cost of US\$ 818 billion (WHO, 2015)), affecting negatively their caregivers as well due to burnout, it will be critical to provide opportunities that allow people with dementia to remain active and independent as much as possible, to be engaged in the community. Leisure and tourism is one of these options, that also help to slow down the progress of dementia, and in particular ss able to reduce behavioral problems. These people, in the early stage of the disease, that lasts 7-10 years (WHO, 2012), maintain a sufficient level of physical, cognitive and behavioral abilities to enable them, if assistance is given, to travel and to be involved in tourism activities. Tourism activities, activities in the open air, and physical activities are in fact beneficial for people with dementia, limiting their behavioral and cognitive problems (Dupuis et al., 2012; Genoe, 2010; Zeisel, 2009; Mapes, 2013; McNair, 2013), providing support for caregivers as well. Actually the entire health system will also benefit, since this provides significant saving to the entire health system (Graff et al., 2008). Live well with dementia is possible if adequate support is given to people with dementia and their

caregivers (WHO, 2012). According to the literature it is then possible to conclude that if policy makers and entrepreneurs invest into this niche market, creating tourism opportunities, they might be able to obtain important business outcomes as well, as also underlined by Page et al. (2014).

However, although such a good opportunity is visible, a little has been done in researching the willingness of this target market to participate in tourism activities. This paper provides further insights into it, to provide evidence of the fact that also people with dementia and their caregivers would like to be involved in such practices.

Methodology

To give further insights into the willingness of the people with dementia and their caregivers to be involved in tourism activities, an exploratory qualitative research was used. This is based on Grounded Theory (Glaser & Strauss, 1967), and Charmaz (2006) approach to Grounded Theory inspired the analysis. Semi-structured interviews were coded and analyzed with the support of NVivo for Mac 11.1.1. Face to face interviews, tape-recorded with the approval of the interviewee, were transcribed verbatim, to avoid recall bias. Non-probability sampling was used to identify the sample of informal caregivers. The total sample size is of 15 caregivers living in the North of Italy and being either spouses or children of people with dementia. Their age ranges from 40 to 80-year-old; the majority of the people interviewed were females, and the majority of them were assisting people with mild dementia. For this research findings here presented have with significant insights.

Results

The aim of the paper was to understand the willingness of participating in tourism activities of people with dementia and their caregivers, in order to get a clearer understanding of the demand before suggesting policymakers and entrepreneurs to invest in dementia tourism.

Among caregivers there is a positive consensus towards tourism activities. They would like their beloved one to join these activities, and they would like to take part to them as well. In order to be able to make them participate it is important to involve people in activities that they like, trying, whenever possible, to be as much personalized as possible. The essential request is to provide support in dealing with caring for people with dementia in their day-to-day activities when on holiday, and give them care in supporting them during lunch and dinner and when on public transportation.

According to our findings, obtained by analysing interview content through content analysis, there are several factors that influence the willingness of people with dementia and their caregivers of participating in tourism activities (Figure 1). These factors are summarized in the following figure. After the figure further insights are given to explain these factors and their relationship with the willingness of participating in tourism activities.

Figure 1. Willingness of participating in tourism activities: the model (Authors' Own)

The degree of willingness to participate in tourism activities depends on the characteristics of the person with dementia, caregivers' characteristics, person with dementia and caregivers' needs and the family relationship with their leisure time.

As it is possible to imagine the cognitive and behavioral characteristics of the person with dementia influence their ability to join tourism activities. Only those people that have maintained sufficient cognitive abilities and do not have severe behavioral problems might be able to join tourism activities. This is a precondition to enable them to enjoy the tourism benefits, showing lower problems related to transportation and to the adaptation to a new environment. People with dementia might join these activities by themselves, but it is very interesting to see that caregivers would like to join as well. As reported by some caregivers interviewed, the tourism offer could offer as well respite opportunities for them without abandoning their beloved one, and it is also an option of respite for people with dementia. This gives an opportunity for both to share happy moments together far from everyday difficulties.

Although it is possible to see enthusiasm behind this opportunity, there are some skeptical caregivers as well. If caregivers see tourism and leisure activities positively there is a higher level of opportunity to see them be willing to participate in tourism activities. If they are not positive, see only barriers, instead it might be difficult to have them be willing to join and have their beloved to join as well. This shows that the perception of the caregiver is essential when it comes to the willingness to participate in tourism activities. The type of behavioral problems that the person with dementia shows influences their perception. The type of family bond that exists between the person with dementia and the caregivers also influences this perception: husbands and wives are more likely to join tourism activities. Another essential aspect to take as well into consideration is the family relationship with leisure (lifestyle, and participation in tourism activities in the beginning of the disease). It is more likely for families to be interested in tourism activities if the family loved tourism and leisure activities before the disease and in the beginning of it.

Representative quotes of the different themes identified in our analysis are summarized in the following table (Table 1). They represent the elements linked to the factors that

influence the willingness of people with dementia and their caregivers to participate in tourism activities.

Table 1. Representative Quotes Underlying Different Themes – Willingness to join tourism activities (Authors' Own)

Theme 1: Characteristics of the person with dementia
Level of cognitive impairments/ Level of behavioural impairments – At the beginning my mother was diagnosed with Mild Cognitive Impairment. This allowed us to do more activities. At the moment she has dementia, and her Mini Mental is 15. – Until last year he was able to go outside by his own. In the first years of the disease my father and my mother were tourists. They were travelling in a group, where everybody knew about the disease and understood very well the situation. When the cognitive problems and the behavioural one became too difficult to handle, my parents stopped travelling. – The cognitive impairment is highly visible, but she is still able to walk, she goes for a stroll very often, she might benefit from some further physical exercise: she likes dancing
Theme 2: Caregivers characteristics
Family Bond – My mother in law used to go on vacation with the husband. – I went on holiday with my mother. We were happy together. – We go walking together, we spend time together
Perception of tourism as a beneficial activity – This is a very interesting idea. It would be lovely to join tourism activities that allow the person with dementia to socialize, and for us to enjoy good time with together, enjoying some respite – Tourism for people with dementia is idyllic. Those that are sick they do not care about tourism. Tourism is for seniors and not for people with dementia. – When she is involved in leisure activities she smiles, although later on she does not remember what just happened – Leisure activities are beneficial, if somebody helps us, especially for lunch and dinner, we could still go for some small trips – If somebody helps us while travelling, this is my main concern, tourism activities could still be beneficial for us
Theme 3: Person with dementia and caregivers 'needs
Need of diversion – It is important to provide diversion to people with dementia – We hike a lot while we were on holiday. We went as well to the SPA. This helps to break the routine – She likes socializing, this is something she really enjoys: she likes the theatre – He likes to go walking and be in places with people: otherwise he gets bored Need of respite – Caregivers need some respite. – It is important for both to spend some time by ourselves – I would enjoy see her happy: this will help me as well – I would like to participate in leisure activities as well Need to enjoy time together – If tourism activities allow me to stay with my wife but also have sometime for myself, it will be great. – We go walking together – We used to travel together

Theme 4: Family relationship with leisure time

Lifestyle before dementia

- We were not used to be tourists
- He was not used to spend a lot of time in leisure activities
- She was used to go out, to go to the mountain
- We used to be tourists, nowadays I am not willing to do it anymore, she is too much compromised
- He used to go to work and fishing

Past experience of tourism in the early stages of dementia

- My mother and me went to several different destinations as tourists, even after she was diagnosed with dementia.
- My mother in law used to go with the husband on holiday in the beginning of the disease. She went as well last year with her formal caregiver.
- Until last year we used to take the train together and go for short trips to Laveno, Lake Como, etc. Unfortunately, now we cannot go for lunch or dinner in a restaurant, she has eating problems.
- She always liked to be involved in leisure activities, be surrounded by people

Discussion and conclusion

This analysis allows us to build further understanding on dementia tourism. It is possible to confirm that there is an interest in this form of tourism and those policy makers and entrepreneurs that will decide to be dementia friendly might be able to succeed. However, it is not possible to assume that people with dementia and their caregivers will be interested in tourism. Integrating dementia into a destination development strategy is an enviable objective, as also stated by Page, et al. (2014), but it is challenging and requires further understanding. Challenges are linked to people with dementia and their caregivers' characteristics, lifestyle and needs. These aspects affect both positively and negatively the willingness of this target market to be involved in tourism activities. Dementia friendly tourism represents an innovative solution for rejuvenation, but it is essential to handle it with care, without assuming that the supply driven initiatives will actually succeed although they are very good in their intentions. Some caregivers in fact won't participate in these activities due to reasons seen before in the result part. This brings us to the conclusion that any business willing to develop such an offer should further research the market needs before investing in such offers. It is as well extremely important to remember that this offer requires adaptation to the existing offer since people with dementia need further support in terms of care. This could be considered as a challenge but at the same time it is an opportunity also in the light of identifying future employment opportunity and new vacancies in the market.

Abstract. Corporate social responsibility (CSR) has gained increasing attention over the past decade arguing that business returns from CSR depend on the way the stakeholders perceive socially responsible practices. Previous research mostly investigated customer perceptions, leaving employee perceptions in the sidelines and accordingly neglecting employee importance. In this context, one more gap is related to attempts to understand the impact of CSR on organizational outcomes. While many studies typically examined the impact of CSR on financial performance or customer satisfaction, scarce research has been done to find the influence of CSR on employees. Although recently the number of studies linking CSR and employee-related outcomes has been growing, nevertheless employee attitudes, such as organizational commitment or job satisfaction, dominate; meanwhile employee behavior, including organizational citizenship behavior (OCB), receives less attention. Thus, the linkage between CSR and OCB remains largely unexplored, whereas OCB can be a source of competitive advantage. Trying to close the gap, the paper aims at revealing the relationship between employee perceptions of CSR and OCB. In doing this, quantitative data were collected (307 responses in total). Consistent with the expectations, the survey indicated that employee perceptions of CSR directed at four main stakeholder groups, namely social and non-social stakeholders, employees, customers and government, had a positive effect on OCB. As regards relationship based on separate dimensions of OCB, distinct findings were revealed. As it was expected, employee perceptions of CSR towards customers and also towards government have a positive effect on each of five OCB dimensions. Slightly different findings appeared in cases of employee perceptions of CSR towards social and non-social stakeholders and also towards employees. As regards the first case, no statistically significant relationship between perceptions and altruism and sportsmanship was found. Meanwhile in the second case, no statistically significant relationship with sportsmanship was discovered. Generally, the provided result underlines the necessity for business to invest not only in CSR, but also in employee perceptions of CSR, as this could drive extra-role employee behavior, namely OCB.

Keywords: corporate social responsibility; organizational citizenship behavior; employee; employee perceptions; stakeholders; social identity theory

Introduction

In recent years, there has been growing acknowledgment that CSR is relevant for organizations individually, as there is “certainly profit to be made from sustainability and losses may occur if sustainability is overlooked” (Harry, 2014, p.405). Although there are many definitions of CSR, the Green Paper (Commission of European Communities, 2001) describes CSR as “a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis” (p. 8). Generally speaking, CSR refers to organization’s awareness of how its actions impact on stakeholders addressing the necessity to serve the needs of multiple stakeholders (Lee, Park & Lee, 2013), as “any stakeholder relationship may be the most critical one at a particular time or on a particular issue” (Post, Preston & Sachs, 2002, p.8). Thus, in this context, it is important to understand how different stakeholders perceive CSR activities pursued by organizations, as CSR has a positive impact on organizations’ competitiveness (European Competitiveness Report, 2008). Whereas till now, the majority of the existing studies on CSR investigated consumer perceptions (Öberseder et al., 2014), the paper fills the gap by focusing on employee perceptions of CSR arguing that employees are relatively highly salient stakeholders to whom the organization owes a perfect duty (Greenwood, 2007).

Turning to CSR impact on organizational performance, customer satisfaction and financial performance seem to be typical outcomes that have received most empirical attention (Lee, Lee & Li, 2012; Zbucha, 2013). A more recent focus on the broader CSR influence understanding includes employee-centered approach (van de Voorde, Paauwe & van Veldhoven, 2012) by examining the effect on the employee attitudes such as organizational commitment (Bramer, Millington & Rayton, 2007; Hofman & Newman, 2014) or job satisfaction (Valentine & Fleischman, 2008). Still and all, the impact of CSR on employee behavior, including OCB, has been largely neglected and remains underdeveloped (Carmeli, Gillat & Waldman, 2007; Rupp, Shao, Thornton & Skarlicki, 2013; Zhang, Fan & Zhu, 2014; Newmann, Nielsen & Miao, 2015). Originally defined by Organ (1988), OCB refers to “individual behavior that is discretionary, not directly or explicitly recognized by the formal reward system, and in the aggregate promotes the efficient and effective functioning of the organization” (p.4). Generally, OCB is considered as “individual citizenship” in the organization and reflects individuals’ extra-role behavior involving “going beyond general expectations to promote the effective operation of the organization or to benefit others in the organization” (Lin et al., 2010). Drawing on Organ’s (1998) fundamental assumption and later supporting empirical evidences that OCB enhances organizational performance (Podsakoff, MacKenzie, Paine & Bachrach, 2000), the antecedents of such behavior become of high importance. As it was mentioned before, although CSR is well recognized in the literature as the antecedent of employee attitudes, the question still remains how employee behavior, in terms of OCB, may be driven by CSR perceived by employees. The paper seeks to close this gap analyzing the relationship between employee perceptions of CSR and OCB.

The purpose of this paper is to deepen the current analysis in the fields of CSR and OCB by revealing the relationship between CSR directed at four stakeholder groups and OCB, including its dimensions. In doing this, the paper seeks to answer the following: How can CSR be defined and what are its dimensions? Why is it important to take the employee perspective into consideration? How can OCB be defined and what are its

dimensions? Will the CSR practices perceived by employees result in a positive effect on employee OCB towards a particular organization?

The paper contributes to literature in several ways. Firstly, as a possibility to operationalize and better understand CSR perceived by employees, mostly the following pathways have been suggested in the literature: to organize CSR practices by stakeholder types (Park & Levy, 2014), to use global measure of CSR or to imply CSR practices directed to a single group of stakeholders (Newman et al., 2015). The paper contributes to the first stream by distinguishing between CSR practices towards different stakeholders. This allows enriching literature not only on CSR, but also on stakeholder management. Secondly, the paper responds to the call of Podsakoff et al. (2000) to provide empirical studies that include multiple forms of OCB and test of the differences in the strength of the antecedents. In doing this, the paper analyses if CSR has a different effect on the five dimensions of OCB. Thirdly, the paper provides empirical evidence suggesting for the organization to invest in CSR activities, as employee perception of CSR has an impact on employee behavior, namely OCB.

The paper begins by examining the literature on CSR and OCB and developing hypotheses. The research methodology is then outlined. Following this, the results of the research will be presented and discussed. Last, the paper provides some general conclusions before indicating some future research avenues.

Theoretical background

Corporate social responsibility and employee perception of it.

Drawing on the previous literature, CSR commonly refers to the relationship between business and society, which denotes organization's actions to balance financial performance and impact on environment and society (Park & Levy, 2014). Thus, CSR is seen as a business approach arguing that organizations have a broader range of obligations besides financial and economic ones (Costa & Menichini, 2013). In this context, broadening (expansion of) the scope of responsibilities translates into benefits for organizations themselves. Favorable perceptions of consumers, positive attitude of current and future employees towards the organization or business partners' willingness to do business with the particular organization serve as convincing examples of such benefits created by CSR (Lee et al., 2012). Generally speaking, organizations engaged in CSR perform better (Gallardo-Vazquez & Sanchez-Hernandez, 2014).

The given understanding of CSR, particularly the definition provided in the Green Paper (Commission of European Communities, 2001, see Introduction), allows to conclude that CSR is closely interrelated with concept of "stakeholder" (Turker, 2009a); moreover, it has its roots in stakeholder theory (Friemann, 1984). The central proposition of stakeholder theory relies on business engagement with all stakeholders, defining them as "any individual or group who can affect or is affected by actions, decisions, policies, practices or goals of an organization" (Freeman, 1984, p.25). However, rationality and limited resources force businesses to classify and prioritize the pool of stakeholders (Mitchell, Agle & Wood, 1997). Independent of the classifications provided in the literature (Rodrigo & Arenas, 2008; Wereda et al., 2016), employees are seen as highly salient stakeholders (Lee et al., 2013). However, the employees are often neglected in CSR research giving the priority to customers (Öberseder et al., 2014). Such

fact is particularly troubling at least due to one reason. The previous literature provides the support for idea that business returns of CSR depend on the way the stakeholders perceive organization's socially responsible practices (Costa & Menichini, 2013). In this context, the negation of employees', as a key stakeholders', perceptions can result in negative consequences for the organization, as "employees determine quality of the product/service customers receive" (Lee et al., 2012, p. 745). Moreover, Rupp et al. (2013) argue that employee perceptions of CSR may actually have "more direct and stronger implications for employee's subsequent reactions than actual firm behaviors of which employees may or may not be aware" (p. 897). Thus, the provided argumentations support the idea to include the employees' "subjective point of view, related to the experience and personal opinion" (Costa & Menichini, 2013, p.152) in research, defining employee perceptions of CSR as "a degree to which employees perceive a company supports the activities related to a social cause" (Lee et al., 2013, p.1717).

Organizational citizenship behavior

The interest in OCB has stemmed from the belief that such behavior enhances organizational effectiveness (Podsakoff & MacKenzie, 1997; Podsakoff, Whiting, Podsakoff & Blume, 2009). Following Bolino and Turnley (2003), an organizations' ability to elicit employee OCB "can be a key asset and one that is difficult for competitors to imitate" (p. 60). For gaining a better understanding on this competitive advantage, the literature mainly addresses three aspects: definitional and dimensionality variety and the antecedents of OCB.

Originally, OCB was defined by Organ (1988) arguing that OCB is work-related behavior expressed by three features: discretionality, non-recognition by the formal reward system and promoting efficiency and effectiveness of a particular organization. Later, Organ (1997) provided a more precise understanding of OCB referring to "performance that supports the social and psychological environment in which task performance takes place" (p. 95). Bolino and Turnley (2003) define OCB as employee efforts that go "above and beyond the call of duty". Several years later, Bolino and Turnley (2005) underlined that in OCB, engaged employees "go the extra mile for their organizations and thereby contribute to its effective functioning" (p. 740). Moormann (1991) treats OCB as a non-traditional type of job behavior, whereas, according to Organ (1988), OCB reflects "good soldier syndrome".

Briefly, the given definitions of OCB indicate two common features. First, as OCB goes beyond formal role requirements, it is not directly enforceable, it is a matter of personnel choice (Chahal & Mehta, 2010). Thus, the threat of sanctions is not working (Smith, Organ & Near, 1983). Second, OCB represents the special or extra efforts that organizations need from employees in order to be successful (Bolino & Turnley, 2003). However, for better understanding of OCB it is important to translate the construct into shared meaning or measured outcomes. Thus, such questions, as *What are the examples of OCB?* or *How is OCB manifested in the daily working surrounding?* should be answered. Lin et al. (2010) provide the following examples of employee OCB: volunteering for extra works, cooperating with others, orienting new staff and helping others in their job. Taking on additional assignments, keeping up with developments in one's field or profession, promoting and protecting the organization, following organizational rules even when no one is looking, or keeping a positive attitude and tolerating inconveniences at work can also serve as examples of OCB (Bolino & Turnley, 2003).

The provided examples partly rely on the dimensionality of the construct. Notwithstanding the different views with respect to the dimensionality of OCB (for detail review see Podsakoff et al., 2000), the two best-known sets of dimensions were proposed by Organ (1988, 1990) and by Williams and Anderson (1991). Organ (1988) originally proposed a five-factor OCB model consisting of altruism, courtesy, conscientiousness, civic virtue, and sportsmanship. However, later the model was expanded by including two other dimensions, namely peacekeeping and cheerleading (Organ, 1990). Williams and Anderson (1991) organize OCB into categories on the basis of the direction of the behavior: behaviors directed at the benefit of other individuals (*OCBI*), and behaviors directed at the benefit of the organization (*OCBO*). Actually, all of Organ's (1988, 1990) OCB dimensions can be captured in Williams and Anderson' (1991) model. As altruism, courtesy, peacekeeping, and cheerleading behaviors are aimed at helping other individuals, these dimensions can be included in the *OCBI* category. Accordingly, conscientiousness, civic virtue and sportsmanship can be a part of *OCBO*. As the paper follows the original view of Organ (1998), the brief description of 5 dimensions is provided below.

Altruism represents helping other members of the organization. It encompasses behavior that covers help for co-workers who are overloaded, absent, or less skilled, or help for new employees in assisting to fulfil their tasks. Such help is provided on a voluntary basis and even when it was not requested (Chahal & Mehta, 2010, Abdullah & Rashid, 2012).

Courtesy includes such behavior as being mindful of how one's behavior affects others and attempting to prevent and avoid work-related problems with others (Lin et al., 2010).

Conscientiousness refers to behavior when employees accept and adhere to the rules, regulations, and procedures of a particular organization (Podsakoff et al., 2009). Obeying the rules, following time breaks, and never wasting work time are the elements of conscientiousness (Chahal & Mehta, 2010).

Sportsmanship is perceived as "a willingness on the part of employees to tolerate less than ideal circumstances without complaining and not making problems seem bigger than they actually are" (Podsakoff et al., 2009, p. 123). Several aspects are part of sportsmanship: not complaining when people are inconvenienced by others; maintaining a positive attitude even things do not go their way, not being offended when others do not accept the suggestions; willing to sacrifice personal interest for the group wellbeing, and not taking the rejection of proposed ideas personally (Podsakoff et al., 2000).

Civic virtue represents responsible participation of employees in the life of organization in such forms as attending meetings that are not required or keeping up with the changes in the organization (Abdullah & Rashid, 2012).

Switching to the topic of antecedents of OCB, Podsakoff et al. (2000) concluded that job task variables and different types of leader behavior seem to be the most strongly related to OCB. Thus, previous research suggested that employees are the most likely to engage in OCB when they are satisfied with their job or committed to an organization, when they have supportive or inspirational leaders, and when they receive intrinsic

tasks to perform (Bolino, Turnley & Bloodgood, 2002). This paper attempts to expand the list of antecedents of OCB and joins to the till-now-limited number of empirical papers (Newman et al., 2015) by addressing CSR perceived by employees as a possible driver for OCB.

CSR and OCB relationship: hypothesis development

The prevailing message in the literature is clear – employee perceptions of CSR will trigger emotional, attitudinal, and behavior responses (Rupp, Ganapathi, Aguilera & Williams, 2006). Trying to close the gap in the literature, behavior responses, namely OCB, was chosen. Moreover, following the plea of Podsakoff et al. (2000), the hypotheses are developed not only for the whole construct of OCB, but also for separate dimensions indicated by Organ (1988). Concerning CSR, it should be admitted that CSR is a multi-dimensional construct and often is categorized by the “type” of responsibility. For instance, Gallardo-Vazquez and Sanchez-Hernandez (2014) suggest measuring CSR by incorporating the Triple Bottom Line approach (Elkington, 1998), namely these dimensions: economic, social and environmental. Meanwhile, based on Carroll’s (1991) CSR framework, Lee et al. (2013) propose to measure philanthropic, ethical and environmental CSR. However, Park and Levy (2014) argue that previous studies suggest that CSR practices are better understood theoretically and tested empirically when organized by stakeholder types rather than responsibility types. Following this approach, the paper implies and measures CSR practices directed at four main stakeholder groups, namely: social and non-social stakeholders, employees, customers and government (Turker, 2009b).

Social identity theory (SIT) is employed to explain the relationship between CSR and OCB. SIT suggests that individuals classify themselves as belonging to various social groups, including the organization they work for, and derive either positive or negative self-esteem from such belonging (Tajtel & Turner, 1985; Hofman & Newman, 2014, Brunetto & Farr-Wharton, 2002). A core idea of SIT theory is the statement that the “extent to which people identify with a particular social group determines their inclination to behave in terms of their group membership” (Ellemers et al., 1999, p.372). Thus, organizational identification provides a starting point for employees from which they view and understand “what one should think and feel, and how one should behave” (Hogg, Terry & White, 1995, p.260). Keeping that in mind, the hypotheses are provided below.

CSR towards social and non-social stakeholders. This group of stakeholders encompasses 4 types of the so called secondary stakeholders, who are closely interrelated with each other: society, natural environment, future generations and NGOs (Turker, 2009a). Business practices which seek minimizing its impact on the natural environment, make life better for future generations, support non-governmental organizations and contribute to projects, and activities that promote the wellbeing of society are covered by CSR towards social and non-social stakeholders (Turker, 2009b). From SIT perspective, if an organization engages in the mentioned activities, its employees can be proud of being members of such organization and this leads to increased identification with the particular organization (Turker, 2009b). Additionally, strong organizational identification will lead employees to feel that they have shared values with co-workers and due to these employees will be more likely to engage in extra-role behavior that benefits other members of the organization (Newman et al., 2015). Consistent with these expectations, several studies (Rupp et al., 2013; Zhang et al., 2014; Newman et al.,

2015) have shown that employee perceptions towards social and non-social stakeholders have positive influence on OCB. Therefore, the paper hypothesizes the following:

H1. Employee perceptions of CSR towards social and non-social stakeholders will be positively related to their OCB, including altruism (H1a), courtesy (H1b), conscientiousness (H1c), civic virtue (H1d), and sportsmanship (H1e).

CSR towards employees. Career development opportunities, work-life balance promotion or employee development are only several examples of CSR towards employees (Turker, 2009a). Based on SIT, when employees have positive perceptions that the organization takes care of them and co-workers, they are more likely to feel that the organization shares similar values to their own and as a result develop a high level of organizational identification (Newman et al., 2015). In turn, such identification encourages employees to go “above and beyond the call of duty” for the benefit of others in the organization. Despite these theoretical expectations, empirical results are contradictory. Zhang et al. (2014) found a strong relationship between the general measure of employee perceptions of corporate social performance, including items measuring CSR directed towards employees, and employee OCB. Meanwhile, Newman et al. (2015) found no statistically significant relationship between CSR towards employees and OCB. Thus, based more on theoretical expectations, the paper hypothesizes the following:

H2. Employee perceptions of CSR towards employees will be positively related to their OCB, including altruism (H2a), courtesy (H2b), conscientiousness (H2c), civic virtue (H2d), and sportsmanship (H2e).

CSR towards customers. Turker (2009b) argue that employees seem to be the agents of their employers. This means that if an organization misleads its customers, employees may also feel the shame of this behavior and vice versa, if an organization pays attention to its customers, for instance by providing high quality products, employees may also be proud of being a member of this organization (Turker, 2009b). From the SIT perspective, employees tend to view the success or failure of their organization as a matter of personal success or failure (Hofman & Newman, 2014). Thus, positive feedback from customers will strengthen organizational identification, which will encourage employees to engage in OCB that benefits other member of an organization (Newman et al., 2014). Despite the fact that Newman et al. (2015) found no statistically significant relationship between CSR towards customers and employee OCB, it is hypothesized:

H3. Employee perceptions of CSR towards customers will be positively related to their OCB, including altruism (H3a), courtesy (H3b), conscientiousness (H3c), civic virtue (H3d), and sportsmanship (H3e).

CSR towards government. CSR towards government refers to an organization meeting its obligations under the law and complying with relevant government regulations (Newman et al., 2015). Working for an organization that meets its obligations under the law will increase the employee level of self-esteem and identify with the values of the organization. Further, this leads the employees to put extra efforts and engage in OCBs in order to help co-workers with whom they perceive to have similar values (Carmeli et al., 2007; Bartels et al., 2010). Although Newman et al. (2015) found no statistically

significant relationship between CSR towards government and employee OCB, it is hypothesized:

H4. Employee perceptions of CSR towards government will be positively related to their OCB, including altruism (H4a), courtesy (H4b), conscientiousness (H4c), civic virtue (H4d), and sportsmanship (H4e).

Research method

Sample and data collection. The respondents chosen to gather the data and test the hypotheses were working-age employees in Lithuania. The research was based on criteria of convenience in order to get the data from the respondents who are easier to reach. The questionnaire was distributed online. Data collection took more than 2 months. At the end of the research, 307 questionnaires were collected and, according the number of working people in Lithuania, such amount of responses reflects 5.5 % of error which indicated the reliability of the data. Table 1 provides a profile of the respondents.

Table 1 Respondents' profile

Characteristics	Frequency (n)	Percentage (%)
<i>Gender</i>		
Female	193	62,9
Male	114	37,1
<i>Age</i>		
18-25	163	53,09
26-32	43	14,0
33-41	36	11,73
42-52	48	15,64
53-65	17	5,54
<i>Position</i>		
Holding a managerial position	50	16,3
Holding another position	257	83,7

Measures. OCB was measured using Podsakoff, MacKenzie, Moorman and Fetter's (1990) OCB scale (cit. Fields, 2002), which includes 24 items. Respondents were asked to indicate their agreement with each statement on a 5-point Likert scale, where 1 means strongly disagree, 5 – strongly agree. This instrument measures the five dimensions of OCB, namely altruism (5 items), courtesy (5 items), conscientiousness (5 items), civic virtue (4 items), and sportsmanship (5 items). These subscales had Cronbach's alpha of 0.885; 0.796; 0.736; 0.691 and 0.731 respectively.

Employee perceptions of organizational CSR was measured using Turker's (2009a) scale, which encompasses 4 subscales: CSR practices towards social and non-social stakeholders (8 items), employees (5 items), customers (3 items), and government (2 items). Respondents were asked to indicate their agreement with each statement on a 5-point Likert scale, where 1 means strongly disagree, 5 – strongly agree. The subscales had Cronbach's alpha of 0.896; 0.851; 0.711 and 0.713.

Results

The means, standard deviations for the scales and correlation matrix are provided in Table 2. Referring to Table 2, hypotheses H3 and H4 were fully supported, while hypotheses H1 and H2 were partially supported. However, in all cases, the relationship between employee perceptions of CSR towards different stakeholders and OCB (and its dimensions) was very weak ($r < 0.2$), weak ($r < 0.2 - 0.4$) or of average strength ($r < 0.4 - 0.7$) (Burns, 2000). Employee perceptions of CSR towards customers (H3) was found to have a statistically significant positive effect on OCB ($r = 0.515$, $p < 0.01$). Concerning different dimensions of OCB, employee perceptions of CSR towards customers had the most significant positive effect on courtesy ($r = 0.549$, $p < 0.01$) and a less significant effect on conscientiousness ($r = 0.248$, $p < 0.01$). H4 was confirmed almost in the same manner as in the case of H3. Employee perceptions of CSR towards government was found to have a statistically significant positive effect on OCB ($r = 0.468$, $p < 0.01$). Concerning different dimensions of OCB, employee perceptions of CSR towards customers had the most significant positive effect on courtesy ($r = 0.402$, $p < 0.01$) and a less significant effect on sportsmanship ($r = 0.282$, $p < 0.01$).

H1 was supported partially. Employee perceptions of CSR towards social and non-social stakeholders was found to have a statistically significant positive effect on OCB ($r = 0.315$, $p < 0.01$). However, referring to different dimensions of OCB, no statistically significant relationship was found in regards to altruism and sportsmanship. Very similar situation concerning H2, as no statistically significant relationship was found between employee perceptions of CRS towards employees and sportsmanship.

Discussion

The purpose of this paper was to reveal the relationships between the employee perceptions of CSR towards four stakeholders' groups and OCB, including its five dimensions. Generally, results supported all hypotheses raised concerning OCB, strengthening the basic premise that positive employee perceptions towards different stakeholders will result in higher employee OCB. However, in the case of OCB dimensions, namely altruism and sportsmanship, the results were slightly different.

Results referring to employee perceptions of CSR directed at social and non-social stakeholders demonstrated the existence of a positive relationship with OCB, emphasizing that socially and environmentally responsible practices pay off and lead to increased identification with the organization. These findings are in line with the study of Rupp et al. (2013) and support the conclusion of Newman et al. (2015), that "commitment to such practices is likely to reap organizational rewards in promoting employees' extra-role behavior" (p.1238). Further, it is relevant to note that the same positive relationship was found in different geographic contexts: China (Newman et al., 2015) and Lithuania. Thus, the findings strengthen the idea that the employees are concerned about the natural environment, future generations and life of society in whole. More specifically, employees feeling that the organization cares "about the present and future of world" (Turker, 2009b) results in a sense of pride in working for such an organization, and further, increased identification with organization fostering extra-role behavior.

**p<0.01. *p<0.05

Turning to relationship between employee perceptions of CSR directed at social and non-social stakeholders and five OCB dimensions, no statistically significant relationship was found in cases of altruism and sportsmanship. The explanation for such findings may result from context or working setting in which the research was conducted. One of the frightening features of working setting is workload. Thus, due to workload employees may not be willing or even have no time to help other members in the organization in their tasks or be not willing to accept less than ideal working circumstances. Employees may feel that instead of supporting environmental, non-governmental or other initiatives, some organizational resources should be allocated to improvement of their working conditions.

As it was expected, positive relationship between employee perceptions of CSR directed at employees and OCB was found. Thus, taking care of employees in terms of increased workplace flexibility, career development opportunities, fair treatment or considering employee needs (Turker, 2009a), create the perception that the organization shares similar values to those of employees. This in turn, following the empirical conclusion on CSR and identification of Carmeli et al. (2007), increases the employee identification with the organization and their willingness to behave in such a way that benefits other members of the organization. Incidentally, the findings of the paper are inconsistent with the findings of Newman et al. (2015), but this might be explained by different working settings. Turning to separate dimensions of OCB, no statistically significant relationship between CSR directed at employees and sportsmanship was found. It could be argued that employees are not willing to tolerate organizational difficulties or inconveniences, or accept work-related problems without complaining (Boiral, 2009).

Consistent with the expectations, the findings revealed that the perceived CSR towards customers results in a higher level of OCB and each of its dimensions. Such results support the idea that employees interact closely with customers (Turker, 2009b) and the feedback from customers or organization's actions directed to customers and consequences of such actions is interpreted on a personal level. The sharing of success in regard to customers encourages employees to do more in terms of OCB. It seems that better treatment of customers pushes the employees towards higher altruism, courtesy, conscientiousness, sportsmanship and civil virtue. As in the previous case, the findings of the paper are inconsistent with the findings of Newman et al. (2015), which found no statistically significant relationship between CSR towards customers and OCB, but this might be explained by different working settings.

Finally, not surprisingly, employee perceptions of CSR directed at government were found to be positively related to OCB and each of its dimensions. Considering that some businesses still do not follow the legal requirements and try to avoid paying taxes or to pay less, the employees are more willing to work for organizations which are more socially responsible and, accordingly, to put extra efforts, resulting in OCB.

Conclusions

Following the idea that is well-established in literature that organizations benefit from CSR depending on how these socially responsible practices are perceived by different stakeholders, the paper aimed at revealing the relationship between the employee perceptions of CSR towards four stakeholder groups and OCB. The results demonstrated that employee perceptions of the organization investing in CSR towards social and non-

social stakeholders, employees, customers and government may lead to the greater exhibition of OCB by employees.

The paper provides several practical implications. Practitioners will benefit from considering CSR in order to foster OCB. It seems that employee perceptions of CSR directed at customers and government have a potential to encourage employees for higher altruism, courtesy, conscientiousness, sportsmanship and civil virtue. More generally speaking, the research showed that practitioners should not neglect the perceptions of employees as highly salient stakeholders.

The paper has certain limitations that suggest the directions for future research. It might be impossible to generalize the outcomes of the research to other geographic contexts. A large-scale study or study including employees from different countries might yield the results that could be transferable outwards. Another limitation is related to methodology, as the paper did not control the extent to which the employees were involved in CSR initiatives. It could be possible that the level of involvement predicts the perceptions of employees, and further, the relationship between the perceived CSR and employee OCB. Finally, considering CSR as an antecedent of OCB, this paper did not examine the consequences of OCB. Future research could further develop a holistic model that incorporates both antecedents and consequences of OCB.

Abstract. *A new strategy to revamp Italian economy must enhance potentialities of internal market and of needs of citizens. This article suggests that taking care of the historical-monumental goods could be good in order to boost the economy towards sustainable growth, provided that everything takes place in close partnership with the stakeholders also through public-private partnership (PPP). This study examines the case study of the Agenzia del Demanio and the potential and policies it has undertaken. The conclusion to be pursued is that the enhancement and redevelopment of the territory must be based on economic integration and tourism, which is one of the main sectors driving economic development of different territories. It has to be implemented in a sustainable manner, combining the needs for use of the attractors and the safeguard of the heritage as a precious entity to be preserved, transmitted and handed down to future generations.*

Keywords: *Sustainable development; Agenda 2030; Re-qualification; Public-private partnership; cultural heritage.*

Introduction

Cultural heritage, material and immaterial, is our common wealth: the legacy of the generations that preceded us and ours to posterity. It is a heritage of irreplaceable knowledge and a precious resource for economic growth, employment and social cohesion, which enriches the lives of hundreds of millions of people, a source of inspiration for thinkers and artists and a driving force for our cultural and creative industries. Our cultural heritage and the ways in which we preserve and enhance it are a determining factor in defining Italy's position in the world and its attractiveness as a place to live and work in and visit. Cultural heritage is a shared resource and a common good.

The purpose of this research is to demonstrate that the public administration is able to stimulate the local (and, consequently, national) economy exploiting the endogenous

A characteristics of the territory, enhancing it and pushing the community towards sustainable growth and the pursuit of the SDGs in an innovative way (Sustainable Development Solution Network Report, 2016), i.e. encouraging innovation and growth from abandoned ruins (owned by the State) with limited financial resources and lack of know-how, while satisfying the needs of the territory.

The paper, after providing a theoretical framework focused on the sustainable territorial development, analyses a case study of the Agenzia del Demanio: the "Valore Paese" project, which aims to redevelop and enhance the state property.

Theoretical framework: cultural heritage as a growth strategy

Cultural heritage generates both direct and indirect benefits (Cappellin, 2014). The first ones concern the satisfaction of needs of those who directly use it, the latter are those that cultural heritage can activate in favor of the community. These benefits are both of an economic nature, concerning the increase in employment, investment, tourism, services, infrastructures and trade, and of a social nature, which means development of human capital, creation of a common identity, modelling strong collaborative relationships between citizens and with a general improvement in the quality of life (Barresi, 2013).

However, it is not possible to separate the idea of local cultural heritage as an *asset* for the economic development of a community from the idea of sustainable development. Sustainability concerns the standards of life of a community as it goes to check whether this leads to a healthy and productive life. If development is not sustainable, the impact of enhancing cultural heritage on the local community could be negative. It could undermine the integrity of traditional social systems, determine the cultural conflict with the increasing flow of tourists, the rise of prices of local goods, increased pollution is understood as a negative externality, and more generally a deterioration in the quality of life of the entire resident community (Cicerchia, 2009). On the other hand, if the economic development determined by the enhancement of cultural heritage is sustainable, optimal use of environmental resources is made, the social and cultural entity of the resident community is respected and long-term economic sustainability is assured, guaranteeing more jobs and more income opportunities (Cicerchia, 2009). However, we must consider that the mere presence of a cultural asset is not a guarantee of economic development of the territory, but it is necessary to implement a series of policies (Cappellin, 2014). This must be oriented towards the establishment of a system of integration between cultural heritage and the territorial context of belonging in compliance with the objectives of sustainability (Agenda 2030; ASVISS, 2017; Zbucnea, 2014).

"If a territory fails, the companies that operate in this area also fail and vice versa the success of the companies that insist on it" (Zamagni, 2017). An action of sustainable and local growth based on the valorization of a common good must provide for the pursuit of the SDGs (United Nations, 2016; Sustainable Development Solution Network Report, 2016), through the definition of a program that values the good by making the community an inclusive settlement, safe, durable and sustainable, respecting the SDGs 11 and 15, but also through the involvement of the local community that promotes companies to implement innovation, the SDGs 8 and 9, through collaborative and partnership logics, the SDGs 17. Therefore, development strategies can no longer be

defined by the central government and secondly transferred to territorial community for their implementation. "Rather it is the local that must be able to reacquire its capacity for innovation that has remained so long asleep, during the season of the industrial society" (Zamagni, 2017).

"Local development is not identified [...] with a given model of productive organization but it is built by the ability of local actors to collaborate to produce collective assets that enrich the external economies, but also to enhance common goods" (Triglia, 2005). Those who are the first to actually enjoy these assets are the local citizens and, playing both promoters and users, they are fundamental in the process of local innovation. The latter is an essential tool in terms of competitiveness: by adopting innovative systems for managing and monitoring heritage and cultural activities, it is possible to provide basic support for territorial policies aimed at both citizens and tourists. That the tourist relationship is a composite package of different goods and services and what is known. [...] The success of a territory, or of a city, in the competition between tourist destinations, depends only partly on the endowment of natural (or historical cultural) resources: it depends instead on the ability of the local community to organize a package (i.e. network - Candela, 2012) and offer a product that is firstly and foremost an *experience* (Cellini, 2017). In this way it is possible to build a targeted offer to meet the ever more diversified requests for tourism flows and an increasingly demanding demand, to efficiently manage local cultural sites through the continuous updating of management methods and coordination between all the *stakeholders* (Pultrone, 2013; Zbucheá, 2014).

Case Study: Agenzia del Demanio and project "Valore Paese"

The Agenzia del Demanio is responsible for the management, rationalization and enhancement of the real estate assets. These are real estate for government use, available assets, historical and artistic heritage. The Agency also promotes the enhancement and regeneration of the entire public real estate assets, in synergy with the institutions and local authorities, also identifying innovative and participatory strategies and instruments. The goal is to contribute to the development of the country's economic-productive, social and cultural fabric and to reduce public spending, maximizing the value of goods and optimizing the spaces used by public administrations." (Agenzia del Demanio, 2018). The agency, pursuant to D.lgs. 33/2013 Transparency¹, has structured the "OpenDemanio portal" as an online window that allows citizens, associations, local authorities and entrepreneurs to become aware of the composition of public real estate assets and of investment, recovery and reuse projects. This tool, as well as a dutiful example of transparency, is fundamental for awareness of the community and an incentive to become promoters of initiatives aimed at enhancing cultural heritage (Agenzia del Demanio, sd). Data of the State Balance Sheet give us an overview of the composition of the State Heritage of the Italian distributed at the territorial level (Region and Province) and by category (available assets, unavailable assets, artistic-historical heritage)² about 43.185 assets (Figure 1) for a value of about 60.5 billion (Figure 2) of euros (Agenzia del Demanio, 2018).

¹ Legislative Decree 33/2013 Transparency - New Article 9bis * Database of state-owned properties - Management System (REMS / ADDRESS) * introduced by Legislative Decree 97/2016

² The data of the State Balance Sheet are updated annually, allow you to know the territorial distribution of properties and areas, their category (available assets, unavailable assets, artistic-historical heritage) and their value. Data on the real estate assets of the State under management at the Agenzia del Demanio are

Figure 1. Consistency of the patrimony of the Italian state

Figure 2. Value of the State Heritage

Moreover, we need to distinguish between assets of available assets and assets of unavailable assets (art 828 CC) and historical artistic heritage (Fig. 3). Figure 3 and Figure 4 provide, respectively, an overview of the consistency and value of Italian assets³ from 2014 to 2017: data are reported in aggregate form at the territorial level and distinguishing between land, buildings and their sum (Total State Property).

divided into "Number of assets" and "Value of assets" both at the total level and detailed by type (buildings and non-built assets) and by category (equity available, unavailable heritage, historical artistic heritage). All data are also available by region and by province.

³ The values refer to book inventory values that are not comparable to market values.

Figure 3. Percentage evolution of the consistency of the Italian state assets (by category)

Assets of *unavailable assets* (Figures 4 and 5) represent an average of 49%(figure 3) of the State's consistency. This type of property is subject to the public law regime and intended for use for public purposes (e.g. assets used by the Central Public Administrations, the endowment of the President of the Republic, mines, assets confiscated from organized crime, goods in free and perpetual use to universities and ecclesiastical institutions, public housing not yet transferred to local authorities) (Agenzia del Demanio, 2018).

Figure 4. Consistency of the Unavailable Assets of the State

Figure 5. Value of the Unavailable Assets of the Italian State

The *Historic Artistic Building* (Figures 6 and 7) represents an average of 14% (figure 3) of the State's consistency. The MIBACT recognized a historical, archaeological, artistic and cultural, limiting availability to only a few types and special storage guarantees and proper intended use. Below is the trend from 2014 to 2017 of the amount (Figure 8) and the value of the aforementioned category of assets.

Figure 6. Consistency of the Historic Artistic Building of the Italian State

Figure 7. Value of the Historic Artistic Building of the Italian State

Assets of *available assets* (Figures 8 and 9) represent on average 38%⁴ (figure 3) of the State's consistency and they are managed through the rules of private law (e.g. residential properties, agricultural land, devolved inheritances, donations, vacant real estate, properties devolved for tax debts, interbedded funds, quotas and assets non-strategic residual assets, assets in the process of transfer to Territorial Entities pursuant to State-owned Federalism)¹² (Agenzia del Demanio, 2018).

⁴ The reported value was calculated by the author on data from the State Property Agency and corresponds to the average percentage change from 2017 to 2017.

¹² The reported value was calculated by the author on data from the state property agency and corresponds to the average percentage change from 2017 to 2017.

Figure 8. Available Asset Capital Property of the Italian State

Figure 9. Consistency of the available assets of the Italian State

The Public Administration (Meneguzzo et al., 2012) needs to evolve in order to implement sustainable policies. In this context, the goals of the agency of the State property are regeneration and reuse of properties, enhancing them for triggering revitalization and development processes in the territories concerned. The different reuse projects include assets that are protagonists of administrative, financial and urbanistic paths aimed at maximizing their economic, social and cultural value: to 2017¹³ we count 410 initiatives in Italy (Agenzia del Demanio, sd).

Figure 10. Distribution by status of work progress

¹³ Data updated to December 2017, present on the OpeDate , the state property agency.

Figure 11. Distribution by project type

In 2007 the "*Valore Paese - Dimore*" project was born from the Agenzia del Demanio, Invitalia and ANCI - Foundation of the Common Heritage, with the involvement and participation of the Ministry for Cultural Heritage and Activities and Tourism, the Ministry of Economic Development / Territorial Cohesion, the Conference of Regions and the Autonomous Provinces and the collaboration of other public and private subjects particularly interested in the initiative (Cassa Depositi e Prestiti, Institute for Sports Credit, Italian Association of Confindustria Hotels, Assoimmobiliare, Confindustria, Italian Geographical Society). "*Valore Paese*" is a program for the valorization of buildings owned by the State, kicking off thanks to the 2007 Budget Law, which introduced two important instruments: the granting of valorization for which a property can be rented up to 50 years and "Unitary Valorization Programs", with which it can be planned the redevelopment of public real estates located in the same territory. On the model of the "Paradores" in Spain and the "Pousadas" in Portugal, "Dimore" is a network system of prestigious public properties, such as villas, historic buildings, castles, prisons, barracks, lighthouses, and of receptive-cultural structures diffused on a national scale, to be realized in buildings of great historical-artistic value and in sites of environmental and landscape value with the aim of promoting Italian excellence (nature, art, history, music, fashion, design, creative industry, food and wine) and enhance the tourism-cultural offer, then the development of the territories.

The strategic objective of this operation is to optimize the income generated by the State's real estate assets to favor territorial development and contribute to the productive use of public goods. The project envisaged the transfer of various assets from the Ministry of Defense to the state heritage. The project aims, therefore, at *Ex Immobili della Difesa*, Unique Properties of high value with great historical-artistic value, and the Network Goods, which are inserted in a path of enhancement and redevelopment and then be returned to the community with new functions of social, cultural and commercial type consistent with the needs of local authorities and the community. Assignment of real estate takes place through the Valorisation Concession: an instrument of PPP that allows the development and enhancement of public real estate assets through the assignment to private parties of the right to use real estate for economic purposes for a certain period of time in the face of their requalification, functional reconversion and ordinary and extraordinary maintenance. Through the concession instrument, the private investor does not burden the costs for purchasing properties that remain publicly owned, while the State, in addition to collecting a license fee for the entire duration of the concession, saves the unproductive costs of supervision, custody, safety and maintenance reactivating, at the same time, virtuous circuits of urban transformation and local development. The duration of the concession

is commensurate with the achievement of the economic-financial balance of the investment plan and the related management, for a period of time not exceeding 50 years. For this reason, the assignment for a long period is an important tool capable of guaranteeing redevelopment interventions on capital (investments), using the properties owned by the state as "containers" of economic and social activities. This extension of the rent up to 50 years is intended to attract investors who are genuinely interested, who will be able to amortize expenses over a longer period, but which at the same time will guarantee adequate guarantees on the enhancement intervention and on its duration over time. In this way assets, while remaining property of the State, will be re-qualified and their value will be increased. At the expiry of the concession, the State automatically re-enters the full availability of the properties granted in use, with the acquisition of any transformation, improvement, addition and accession to them.

Sensitivity, and probably an increasingly growing awareness of the winning strategy of revaluing historical and cultural assets, gives rise to a second project within the Value Country program: the *Value Country-Headlights project* that consists of placing public headlights and coastal buildings on the market. In view of Valorisation and redevelopment of the territory, the Agenzia del Demanio in collaboration with Difesa Servizi SpA in 2015 proposed the localization of these assets, an endogenous, irreplaceable and unequalled feature that makes this type of property attractive for innovative and sustainable business projects. The project aims to create a network for the transformation of Italian coastal buildings into a development opportunity for the territories that host them. Figure 14 shows the amount of goods subject to three tenders, made from 2015 to 2017 for the granting of certain structures selected (Value Country lighthouses Agenzia del Demanio, 2018).

Figure 12. Value Country Lighthouses: number of projects (2015-2017)

In the first two years of the project, the agency has assigned 24 facilities to entrepreneurs and associations that will be redeveloped in *lighthouse accommodation*. The social economic impact in the local area estimated by the agency is about 60 million euros, 17 million euros of direct investments and an employment impact of about 300 operators. The last year the project involved two additional regions, Liguria and Marche, and islands of the Venetian lagoon with the release of 17 assets, 9 structures managed by the Agency and 8 by Difesa Servizi SpA.

The "Valore Paese" program has been strengthened in the last two years by a further and ambitious project: *Value Country Routes and Routes*. Promoted by MIBACT and MIT, it has the aim of redeveloping and reusing public buildings located along cycle paths and historical-religious itineraries, containers of services and authentic experiences in line with the philosophy of slow travel. Giving life to this program, the agency seeks to involve many stakeholders, using the tool of public consultation in order

to implement a more rigorous planning making use of the know-how of the private sector, in a logic of PPP, for the benefit of the whole local community. "Recover over 100 public buildings along the paths and cycle-pedestrian and historical-religious routes that cross all of Italy to turn them into hostels, small hotels, food outlets, cycle shops, service and assistance points for all pilgrims, tourists, walkers and cyclists who walk through these tracks every year. Promote and support the development of slow tourism by offering the possibility of reusing public buildings as containers of services and authentic experiences, strongly rooted in the territory: this is the philosophy that moves "Cammini and Percorsi" the new project "network" of the Demanio, promoted by MiBACT and MIT. "(press release Agezia del Demanio, 2017). The "Cammini e Percorsi" project sees today the closure of two calls. The first is a "free leasing for 9 years" closes on 11 December 2017 with 47 offers (14 foreign) and 33 participants (8 cooperatives, 9 associations and 16 companies), and sees the awarding of 13 state buildings, mainly in the center-south, entrusted in "free grant for 9 years" to companies, cooperatives and associations under 40. The second call, recently ended on April 16th 2018, differently from the first one provides for the assignment of 48 public buildings according to the "concession of valorization". This concession provides for the assignment of the asset for a period of 50 years and for the payment of a rent and is awarded the most valid project, or the best investment and local requalification project.

Conclusions

One of the sectors to be exploited and increased to make our country converge towards sustainable development in full respect of the objectives of sustainable development (SDGs) is undoubtedly that of culture, understood both as cultural activities and as cultural heritage.

It is well known that Italy is one of the first countries for its artistic heritage. Despite the activity to date of the State Property Agency, the patrimony of the Italian State is not adequately valued, and its economic, financial and cultural potential is underestimated. Actually, we often discuss about "valorization" of a good in mere economic terms and in a short-term perspective. According to this view, the argument of preservation of the good for both exogenous and endogenous development of the local area is neglected. *Exogenous* development means that the external environment stimulates it and it relates to the attractiveness that the cultural asset exerts on both the flow of tourists and capital investments in that specific area. In this context, the good is appraised as a source of income and investment. Certainly tourism is one of the most dynamic sector of the global economy and, despite the crisis, has maintained its relevance in the positive items of income in the Italian State budget (Pultrone, 2013). Thanks to its positive impact it can both contribute to the resolution of fundamental problems such as the creation of new jobs (implementing the SDGs 8), and be the engine of development for those regions that preserves the traditional territorial and landscape aspects (implementing the SDGs 15). *From an endogenous point of view*, however, in order to be able to self-sustain, the development must start from the local territorial context. Since cultural assets, by nature, are local and relational public goods, they are the first candidates to start such a process. In this way, starting a process aimed at enhancing the endogenous and exogenous characteristics of the good and the local territory, a mechanism of sustainable development is triggered based on the pursuit of the objectives promoted by Agenda 2030 (United Nations, 2016) in particular of the SDGs 11, 17, 8, 9, and 15.

On one hand, it is necessary to take into consideration the protection of heritage, a link between tourists and local community. On the other hand, heritage itself must be promoted, fostering the generation of financial resources in the whole territory. Tourism, as an activity that involves cultural and natural heritage, as well as traditions and contemporary cultures of the European Union, connects economic growth and sustainable development with ethical dimension. The tourism is a major economic activity, with a very positive impact on economic growth and employment in Europe. It is an economic activity capable of creating growth and employment, contributing, at the same time, to the development and economic and social integration, in particular of rural and mountain areas, coastal regions and islands, outlying regions, ultra peripheral or convergent.

Cultural enhancement, therefore, is achieved through processes both at macro-level (involving territorial development and collective well-being) and micro-level (reducing the inefficient use of dedicated public resources). Cultural policies must aim to trigger territorial development mechanisms through the stimulation of synergies that can be activated between cultural heritage and the local economic-productive fabric.

The strategies for the valorization of heritage assets must respect the intrinsic peculiarities of the asset. The Italian State assets, as we have seen, are divided into available and unavailable assets and historical assets, which are differently governed by private and public law. As relational goods they are placed as entities of which more individuals can enjoy together and whose fruition creates bonds and social relationships that contribute to a local identity and relationships of collaboration between citizens. If the recovery of the whole country is a phenomenon that initiates and develops locally, valorization of sites and cultural activities is a crucial factor. It is fundamental to liaise with stakeholders in order to make this strategy efficient.

The sectors connected to the world of culture and heritage are innumerable: in the process of redevelopment, a large number of industries are required to provide different intermediate and final goods. It is easy to see that, by way of example, the opening of a cultural site stimulates the creation of new infrastructures, transport and complementary services (catering services, gadgets), generates new jobs (dramatically increasing the SDGs 8) and stimulates the level of income of residents (dramatically increasing the SDGs 9).

The Program "Valore Paese" implemented by the State Property Agency represents the path to be pursued to achieve a sustainable development (United Nations, 2016) first and foremost national.

In fact, with the three "Value Country-Dimore, Fari e Cammini e Percorsi" projects, the agency seeks to overcome the limits, and to approach the community from a local development perspective, using two tools: public consultation and concession of valorization. The public consultation is an excellent tool for stakeholder engagement as it compares public and private parties in the pursuit of a common goal. The concession of valorization, as a PPP, establishes a virtuous collaboration: large national, public - private investment plan for innovation and projects aimed at improving the quality of life, using cultural historical assets as they give a cultural identity to the individual areas and, consequently, ensure cohesion and synergy between the various sectoral actions of a local development policy. We are witnessing changing roles:

the State, custodian and *dominus* of the public good, stays apart for the most efficient private individual identified through the competitive tender procedure. The focus of the relationship between the principal and the agent (State and private) lies precisely in the greater efficiency of the management of the asset or service delivery, a feature also given by the presence of complete contracts: the Public-Private Partnership (PPP), the signing of *bonus-malus* clauses, sponsorships and constant monitoring in the contractual execution phase allow both an inventiveness on cost minimization and an increase in the level of quality offered. Moreover, the importance of the demand for good or service is fundamental above all in line with the horizontal proliferation of similar market segments. Culture shall be able to generate income and the public must be able to access it: markets with more inelastic demand can finance where it lacks. Ramsey price application can be congenial, as well as it is important that, *ex ante*, tariffs are identified that embrace as many consumers as possible with contract times suitable to ensure that there is a fertile field for investments and retraining of assets.

It is therefore necessary to pay attention when addressing local territory as the starting point: it must not necessarily involve only the local communities. The Value Country Project identifies an extraordinary awareness, and the L. n. 228/2012 has provided that, at the end of the period of time envisaged by the concession, the Ministry of Economy and Finance - Agenzia del demanio, verified the achievement of the purpose of redevelopment and reconversion of assets, can recognize the concessionaire, where there are no needs for use for institutional purposes, the right of pre-emption for the purchase of the asset, at the market price. The DL n. 95/2012 also expressly provided for the possibility of sub-granting to third parties the economic or service activities envisaged in the management plan. This innovation may allow a significant extension of the valorization concession, already tested for the recovery of public buildings for tourism and cultural purposes, to transformation projects that provide for other functional destinations, including residential and commercial destinations.

There is absolutely no need to create monopolies or markets that are detrimental to ex-post competition to the consumer: capital or labor force must be welcome that come from anywhere (Italy and Europe) must be welcome, in presenting projects and offers judged more economically advantageous. The free circulation not only of the workers, but also of the capitals, and how much nowadays these are the manna from heaven. It will be up to investors and management to exploit economies of scale or more simply everything that is productive and that makes local communities participate.

Abstract. *The aim of the research is to analyse the state-of-the-art of Italian railway heritage, in particular the mismanaged stations, disused railway lines, the National action-plan of railway reconversion, the role of the Public Administration in the requalification and regeneration processes and the impact that these processes have on territories in terms of social and environmental sustainability. After an analysis of the literature on the processes of territorial change, such as regeneration and requalification (Borri, 1995; Evans & Shaw, 2004), the research focuses on the analysis of the causes of dismiss and abandonment of the stations and railways and on a cross-country analysis of Italy, Belgium and Spain. The research methodology applied to the case study, mainly qualitative, is based on the document analysis (Bowen, 2009), with the aim of "registering" the unused Italian, Belgian and Spanish railway assets, analysing reuse methodologies and the stakeholder engaged.*

Keywords: *Sustainability; regeneration; requalification; railways sector; greenways; cross countries analysis.*

Introduction

The social changes, urbanization (Gottmann, 1961), migration, economic and technological changes that occurred at the end of the XIX century have significantly changed the territorial infrastructural system. The opening of new roads and railways that provide greater convenience in terms of travel time has often led to the closure of pre-existing railway lines, which have become marginal or technologically obsolescent. Furthermore, the scarce number of users, the equipment made available by technological innovation and the national political choices regarding infrastructures, have led in some cases to the closure of stations and disuse railways, in consideration of management costs that are no longer sustainable or necessary. It is clear that public administration needs to set itself goals for rebirth of the dismissed railway heritage with

a view to sustainability, as requested by the international strategies and regional dynamics on the sustainable development of territorial and urban areas (Agenda, 2030).

The objective of the research is to analyse the impact that regeneration processes have on the territories, by studying how public policies can guide and support sustainable development processes that can achieve positive results in social and environmental terms. After an analysis of the literature on territorially changing processes, such as regeneration and retraining (Borri, 1995; Evans & Shaw, 2004), the authors focused their research on the objectives of these processes, on the stakeholders and on the role held by the Public Administration (paragraph 1). The paper is enriched by a cross countries analysis between Italy, Belgium and Spain (paragraphs 3 and 4) on the reconversion of disused railway networks and an ad hoc interview with the Head of the "Green Station Legambiente" project of Legambiente, a non-profit association that has collaborated with "Ferrovie dello Stato" (Italian railways public company) on projects of regeneration of the dismissed stations. The research methodology (paragraph 2) applied to the case study, mainly qualitative, is based on the document analysis (Bowen, 2009), with the aim of "registering" the Italian, Belgian and Spanish railway heritage not being used, and analysing the methods of reuse, the subjects involved and the reasons for the activation of networks and railway stations.

Literature review

The main changing processes, which see the Public Administration as the principal operator in their implementation, are requalification and regeneration, two of the four processes of change that also include gentrification (Florida, 2002, 2005; Glass, 1964) and self-made urbanism (Litardi, Pastore & Trimarchi, 2016).

Requalification (Borri, 1995) is defined as the transformation of a place (residential, industrial or open space) that shows symptoms of environmental (physical), social and/or economic decline. Retraining is the process that sees "the infusion of a new vitality for communities, industries and places in decline that bring sustainable and long-term improvements in local quality of life, including economic, social and environmental" (Evans & Shaw, 2004).

Regeneration is the rehabilitation of poor or impoverished spaces by the renovation or reconstruction of large-scale housing and public works; when regeneration is considered in the context of "urban", it involves the rebirth or renewal of these. Regeneration is mainly concerned with cities and suburbs facing periods of decline (Litardi et al., 2016).

Requalification is a process that sees a physical restructuring of places and spaces that does not alter the primary use of the space subject to change; the goal of regeneration is to rethink a new use for the place under examination through interventions of a cultural, social, economic and environmental nature, aimed at increasing the quality of life, by respecting the principles of sustainability (Brundtland, 1987) and stakeholder engagement (Jeffrey, 2009).

Table 1. Changing process where Public Administration is the principal operator.
(Source: elaboration from Litardi & Pastore, 2017)

Process	Objects	Pioneer	Stakeholder	Aim/outcome	Results
Requalification	Public space, public building and public service	Public Administration (PA)	Residents and PA	Decoration and renovation	Increasing the value of properties; increasing green areas and public transport services
Regeneration	Private building and public space	Private company, non-profit organization and Public Administration (PA)	Residents, PA, private company, SME, associations	Community aggregation and engagement, Decoration and renovation	Increasing the value of properties; new business; new social and cultural activities; social participation; sense of belonging

Requalification and regeneration could be processes that are not necessarily dependent on each other (Table 1), but when the “pioneer”, i.e. the actor who implements the process of change, is the Public Administration, an attempt is made to implement both processes, for example: “Macro Testaccio” in Rome, a former redevelopment slaughterhouse converted into a museum of contemporary art, the “Greenways” (Little, 1990) in Europe (see paragraph 3) and in New York the “High Line”, a road that crosses the Chelsea district, re-qualified and converted into a real “overhead” park. In particular, the greenways, the object of study of the present research, are defined “as linear open spaces, established along a natural corridor, such as the course of a river, a valley or a ridge line, or long sections of pertinence of infrastructures of transport, such as disused and reconverted railways to recreational uses, or canals and scenic roads” (Little, 1990). In Little’s definition, greenways are also the pedestrian or cycle paths immersed in natural settings, the open spaces that connect parks, reserves, and cultural and historical sites, with populated areas.

Research methodology

The assumption of the research starts from a theoretical analysis elaborated on two of the four principal processes (Borri, 1985; Evans and Shaw, 2004) of urban change: regeneration and requalification, and the pioneers who allowed these processes (paragraph 1). However, the aim of the research is to analyse what kind of sustainable development model has been created in the process of changing greenways at the European level.

The research is enriched by interviews (Kvale, 1996; McNamara, 1999) that the authors have had with key stakeholders of the Italian experience: the General Manager of *Legambiente* Rossella Muroi and the project manager of Green Station *Legambiente* Lorenzo Barucca (paragraph 3 and 4).

Italy, Spain and Belgium are the countries of interest for the cross-country analysis (paragraph 4). The factors for choosing these countries are the quantity of disused railway lines, the modalities of conversion and the causes that led to this divestment (paragraph 3).

The main causes and effects of the disused railways and railways station, are:

- European regulations, Directive n. 34/2012 / EU, establishing a single European railway area through the strengthening of competition rules, such as, for example, the separation between the railway transport service and the ownership of infrastructure through the establishment of an open railway market, eliminating administrative and technical obstacles and ensuring a level playing field with other modes of transport;
- The increase in new technologies applied to the railway sector has made it possible to regulate the movement of trains and manage all the technical operations connected by a single operating post that oversees scheduled sections and controls. These remote operations without the need for the presence of personnel on site, has caused an increase in the presence of railway facilities (stations and toll booths) but depleted the territory due to the lowering of labour supply;
- The urbanization of cities, relative impoverishment of rural areas and depopulation.

Cross countries analysis is enriched by a qualitative research methodology such as document analysis for the review and evaluation of electronic documents (Bowen, 2009). During the research, the information was systematized, summarized and elaborated in order to present a map of the use and interpretation of unprecedented territorial initiatives and their critical reading, on the basis of the main theories and models considered. In particular, the authors organized the parameters into seven specific categories through the information analysed in the documents (Labuschagne, 2003), which helped to have a mapping of the practices, their similarities and distinctions: a) country, b) year, c) object disused, d) pioneers, e) results, f) processes of change, g) type of partnership or concession. This scheme is useful for replicating the study in other case studies and comparing the results.

Cross countries analysis: Italy, Belgium and Spain

Italian scenario

Ferrovie dello Stato Italiane (FS), like other European railway companies, has in recent years engaged in a deep effort to reorganize and redevelop unused real estate assets. These are disused railway lines and stations which now run the risk being vandalised because, due to the technological evolution underway, they no longer need the physical presence of railway personnel, but are remotely managed through IT devices. Currently, there are about 1,700 (see Figure 1) stations of the Italian Railway Network, for the most part in good condition and close to towns, which occupy a total area covered including the station buildings and apartments of about 420,000 square metres, and that were recorded in the FS budget of 1996 with a global value exceeding €200 billion.

The FS Group has started a programme of concessions through free loan contracts for associations and municipalities to launch social projects that have positive effects on the territory and the quality of the services offered at the railways station. Of these, about 345 stations, corresponding to an area of over 63,683 square metres, have been assigned (2014 FS data). Furthermore, a new redevelopment project has been launched for the social and environmental reuse of space thanks to the signing of a "Memoranda of

Understanding” with the Tuscany Region, Legambiente, AITR (Italian Association of Responsible Tourism), CSVnet (Service Centres for Volunteering) and Legacoop Sociali (social cooperative).

Also part of the FS Heritage are 3,000 km of disused railway lines, of which 325 km were destined for greenways: cycle paths and green paths accessible to all, reserved for soft mobility. In particular, for small stations with very low attendance, with no possibility of commercial development, RFI (Italian Railway Network) has activated to stipulate free loan contracts (as defined in Article 1803 of the Civil Code) with Local Authorities or non-profit associations, thus responding to the growing demand for spaces to be dedicated to welfare activities.

These contracts provide for the sale of station premises no longer functional for railway operation to be used for social, cultural, and assistance activities (including, for example, art exhibitions, tourist accommodation, toy libraries, neighbourhood meetings, civil protection, traffic wardens), and assistance to the disadvantaged, (pro loco, etc.). In return it is required that the institution or association takes care of the small maintenance and cleaning of the building. In this way the community is enriched by services structures and guarantees an human presence in the station, with positive effects also in terms of quality and decorum of the structure.

Figure 1. Percentage of disused railways stations on Italian territory

In order to guarantee to the users of the stations an ever better use of the spaces and services and a high architectural and functional quality of the buildings RFI has started several redevelopment programmes at approximately 2,150 stations. In particular, for the valorisation of 101 stations in the south of Italy, significant in terms of location, size, architectural merit and tourist attraction, a project called the “Evolved Program for the Management of Station Areas Located in Southern Italy” (Pegasus Project) is being created.

In 2011 Legambiente signed a Memorandum of Understanding (MoU) with Rete Ferroviaria Italiana (RFI) and FS to promote a policy of support and planning for social initiatives in the railway areas; to enhance central stations as a physical space to offer citizens services and opportunities for meetings; propose new models of development of their territory to make it more sustainable, healthy and attractive; to combat the phenomena of social exclusion of the weakest subjects and to promote the processes of social inclusion. “The purpose of the Memorandum of Understanding - declares Lorenzo Barucca, Responsible for the “Green Station Legambiente” projects - has as its objective

the granting by FS and RFI, to national associations and non-profit organizations, of free loan facilities for communities in order to realize help centre, social and cultural association. This contributes to the construction of a social environment that is the driving force of sustainable development in the city, encouraging the processes of recovery of social trust and the offer of innovative and qualified services. Citizens will be able to take advantage of a kind of “Service Centre” at the station, as well as participate in activities related to the cultural, tourist and social promotion of the territory.

Belgium scenario

Belgium, at the end of the Second World War, had the densest railway network in the world with about 5,000 km of normal railway lines plus another 5,000 km of tram lines. After the war, 1,600 km of normal railway lines and almost all tram lines were abandoned. Towards the end of the 1970s, a unified national policy began to spread for the recovery of this heritage. In Flanders, the national activity was joined by that of the provinces, cities and municipalities that bought or rented the railway offices of disused lines by the SNCB, the national railway company, for the construction of paths that, along with towpaths and country roads, were going to constitute a first network of “greenways”. In the mid-90s, in Flanders over 250 km of disused railway lines had already been transformed into chemins du rail, train paths. In contrast, in Wallonia there had been only isolated and scattered initiatives. In 1987 the Commission du trafic lent promoted the creation of an inventory of abandoned lines: the results showed how the tramlines had been fragmented in such a way that they could no longer be reused for the construction of a network of green routes. On the other hand, the 80 disused lines of the SNCB, with a total length of about 1,000 km, could form the backbone of a network, including also towpaths, cycle paths, walking paths and country roads. In 1991, the Walloons proposed to create a first batch of five lines, identified as great routes for slow traffic, but initially met with some opposition, especially from the SNCB and the Belgian State. However, they continued to pursue the idea of creating a real network of routes reserved for slow traffic, called RAVeL (Réseau Autonome de Voies Lentes), in 1997, a framework agreement with the SNCB was reached, which provided for the concession in emphyteusis of about 1,000 km of disused lines for 99 years. Up to now, 900 km of green paths have been created of which almost 200 km uses disused railway lines.

Spain scenario

In Spain, after the “boom” in rail transport in the early 1900s, when there were about 13,000 km of railway tracks, the decommissioning processes began, which have led today to more than 7,000 km of disused railway lines.

At the beginning of the 1990s a national programme was launched, called Vías Verdes (greenways), coordinated by the Fundación de los Ferrocarriles Españoles (FFE), for the recovery never completed railway lines, for the development of initiatives related to eco-tourism and reuse. The pioneer of the initiative was, in 1993, the Ministerio de Obras Públicas (MOP), Transportes y Medio Ambiente (TMA); today the project is managed by the Ministerio de Medio Ambiente (MIMAM). The Vías Verdes programme is the result of a cooperation agreement between MOP and TMA, which has pledged to allocate €6 million a year for the construction of greenways.

In June 2001, the Spanish National Parliament, “Senado”, unanimously voted for a motion encouraging the Spanish government to improve the necessary instruments and laws in order to convert all the disused railway lines of the country into Vías Verdes, through a procedure involving local and/or regional authorities interested in drafting a feasibility plan, with the collaboration, if requested, of the FFE. Once the land ownership status has been analysed, a design competition is then defined for the redevelopment of the greenway railway line, in agreement with local authorities and associations. Once the feasibility study has been completed, the agreed measures are incorporated into the construction plan, whose insurance can be financed in one of three ways: entirely by MIMAM, co-financed through MIMAM and other regional or local authorities (this is the most used), or through a specific financing project adapted to regional or local conditions.

The positive effect of the greenways on the areas they cross is not limited to the tourism sector, but produces other, very different effects on population and economic dynamics. These effects are more significant when considering rural areas, as in the case of the Sierra Vías Verdes (36 km already built). Here, thanks to the School-Training Laboratory and work programmes, groups of 60 unemployed young people were employed for two years to rehabilitate the four former stations along the greenways and to install tourist facilities. The Sierra Vías Verdes project has allowed the creation of 17 new jobs.

In 2005, 12 years after its launch, the balance of the programme in Spain was very positive. More than €60 million have been invested in converting 1,500 km of disused railway line into 45 Vías Verdes, and there are over 350 km of the project which have already been completed.

Results and conclusion

The disused buildings should remain efficient from a structural and decorative point of view, as continue to be used by railway customers. It is necessary to hypothesize a redefinition of the use of these buildings, also for extra-railway activities, which do not however contradict the use of the station as a service for the community. The reuse activities of the unmanned stations and the railway networks (paragraph 3) can be reconfigured in four macro areas:

- Social: assigning part of the premises of a station to a non-profit association that operates in the field of social services to support the most exposed and indigent population contributes to reinforce the concept of the station as a centre of service provision for the community and it promotes, above all, the continuity of the link with the inhabitants in the smaller centres;
- Tourism: in this regard, in Italy the Department of Tourism has developed a multi-regional plan to boost tourism in the South by financing 447 projects with about €530 billion from the European Union, provided they do not contribute to the further overlap of environmental areas;
- Commercial: establishment of entrepreneurial activities, with particular reference to the Italian law 44 on youth entrepreneurship, or to the recovery of traditional activities of local crafts in danger of extinction within the municipality where the station is located;
- Cultural: cultural activities such as exhibitions, or a museum (also concerning local traditions and customs), library activities, youth orientation to study or work,

educational activities (computer literacy, linguistics, university of the third age) and reconstruction of relational networks (e.g. TimeBank).

In Italy, contrary to what has happened in other countries, a coordination policy has so far been lacking, both at the regional and national level, that is aimed at enhancing the railway tracks no longer being used through the creation of “green routes”. The conversion of the disused railway lines into green routes has, in fact, been sporadic and the result of the initiative of some particularly sensitive local authorities, which have acted without having the necessary reference framework. Until now, an overall vision has been lacking: i.e. to consider the recovery of individual traits as a step towards the creation of a network. This lack has meant that there is no definitive data in Italy about the extension of the disused railway network.

The Spanish scenario is different, as it has designed a precise strategic framework that sees Spanish greenways, “Vías Verdes”, as a strategic factor for economic and social re-launching, succeeding in structuring a programmatic plan that promotes sustainable mobility in the territory, ecological transport, active tourism, sports and various outdoor activities, preservation of abandoned railway heritage, access of the population to nature, and environmental education activities. It is increasingly common for regional or local governments to invest in Vías Verdes projects because they are considered profitable from the point of view of social services and value creation.

Table 2. Comparison between Italy, Spain and Belgium on conversion strategies in greenways

Country	Year	Object disused	Pioneer	Results	Changing process	Partnership
Italy	Second half of 2000	1,700 stations; 3.000 km railway lines	Public Company and non-profit organization	345 station re-qualified, 325 km railway lines regenerated into greenways	Requalification and regeneration	Partnership with associations and loans' concessions
Belgium	Beginning of 1970s	6,600 km railway lines	Public Administration and Public Company	900 km of greenways and 200 km railway lines regenerated into greenways	Requalification and regeneration	Master agreement
Spain	Beginning of 1990s	7,000 km railway lines	Public Administration	1,500 km railway lines regenerated into greenways	Requalification and regeneration	Project financing

The authors compare the greenways programmes of the countries (paragraph 3) by individualising seven indicators (Table 2). Belgium is a pioneering country in the conversion programmes of disused railway lines. The analysis also shows that, while the role of the Public Administration in Spain and Belgium is preponderant, in Italy the Public Authorities are redefining their function in solving problems, reducing the direct intervention to assume the role of “directors” and “facilitators” of the collaboration between companies and third sector realities, but they are not the real pioneers of the redevelopment project. This is done through the enactment of new rules (incentives, tax advantages) that promote bilateral partnerships. Bilateral collaboration, pushing the two realities, the third sector and companies, especially public ones, to work together – albeit with different accents depending on the type – can be a valuable tool for sharing skills and mutual enrichment. “By analysing the phenomenon of partnership between a public company, such as FS, and non-profit, such as *Legambiente*, we can say that Italy holds a position of advantage over other European countries both for the initiatives carried out between these partners and for collaborations with other organizations. In fact, more than 1,700 stations, owned by the FS Group, are not present workers in railways station. Of these, 345 have already been redeveloped with a social focus with 63,683 square meters granted in free loan for a market value of 95,524,500 euros. Today they host Italian social associations, such as: Red Cross, Green Cross, Fire Brigade, Civil Protection, Natural Parks, Environmental or Cultural Associations”, said Barucca.

The FS Group as therefore adopted a policy of support and planning for social initiatives in the railway areas, in agreement with associations and local authorities. At the beginning some of these projects for social utility regarding the assignment of the territory of the stations, were signed with the Regions (Local Authorities) but the results were uncertain, negative and disappointing on the part of the latter. Through the bids-application, each association may request a loan to develop services and infrastructures necessary for the development of the territory, its communities and projects. The projects of the MoU will have a focus on regenerating spaces within railway stations and junctions, understood no longer as just places of arrival and departure but increasingly as meeting places, as well as poles of urban attraction, and social, environmental and collective mobility service centres, concluded Barucca. In this way “Green Stations” project regarded as having solidarity with the territory, a piece of economy that can produce values, such as trust, social capital, civic sense, solidarity, together with economic value and new opportunities. These projects contribute to the creation of a network of social relations within the territory, starting from these structures that for decades have evoked movements, hopes, and dreams of a better life.

It is not a matter of redesigning the disused railway lines but of activating integrated actions to recover disused infrastructures and buildings, coherent with the requirements dictated by new ways of using these goods “networks” (Torella, 2010).

It is desirable to think that these operations should allow, in the long-term, strategies that are without additional costs for companies in the railway sector, the preservation and maintenance of the structural efficiency of the building, the cleaning of the entire station area and the care of the spaces, green annexes, the surveillance of the building and of the areas open to the public and, where possible, services to railway customers.

Abstract. *The European Union (EU) draw up a strategic for the time period 2011-2014 related to corporate social responsibility. In this vein, it is published the Directive 2014/95/UE about non-financial and diversity information by certain large undertakings and groups. This directive is focused on the importance of businesses divulging information on sustainability such as environmental, social and employees matters, related to human rights, anti-corruption and bribery aspects. According to the above arguments, the purpose of this investigation is to analyze the non-financial information about anti-corruption and bribery through a disclosure index in European firms. Namely, we have analyzed the Eurostoxx 50 in 2017 in order to know the disclosure of information related to the above directive about the fight against corruption and bribery. We find that the level of corruption and bribery disclosure in our firm sample is around sixty percent. In particular, the corruption and bribery aspects more disclosed are related to the anti-corruption policies, procedures and standards; internal and external control processes and resources allocated to preventing corruption and bribery; and criteria used in corruption related to risk assessments. Together, these results have public policy implications because they suggest that firm are responding to the disclosure of corruption and bribery information. However, we should highlight that there is still a long way to get disclosure about corruption and bribery from all companies.*

Keywords: *Directive 2014/95/EU; corruption; bribery; Disclosure index.*

Introduction

The financial crisis started around 2008, led to a loss of confidence of society related to financial information provided by organizations, which had repercussions in the reinforcement of the information transparency in order to recover the legitimacy which is lost (Garralda, 2015). All this, based on regulations, recommendations, standards and others. In this regard, the European Commission published in December 2012, an action plan on organization rights. This action plan identifies three priority lines as main

actions such as the promotion of transparency, the involvement of shareholders in corporate governance and support for growth and competitiveness of organizations. The above-mentioned plan aims to promote transparency, through the disclosure of better information from organizations to investors and society. In this regard, it was said the intention to incorporate the obligation to report on social and environmental issues, through a reform of the accounting directives, foreseeing the possibility of including such information in the annual accounts (Quijano, 2013). Subsequently, in November 2014, was published the Directive 2014/95/EU of the European Parliament and Council of 22 October 2014, amending Directive 2013/34/EU, related to disclosure of non-financial information and information on diversity by large companies and certain groups.

The Directive 2014/95/EU determines that those organizations considered of general interest must specifically report on certain issues related to social and environmental impacts. Accepting this requirement, that supposes a high degree of transparency, is the necessary condition to manage the reputational risk, whose cost, in the case of being subjected to a media campaign or a complaint, can be very high for an organization (Garraalda, 2015).

According to the aforementioned Directive, the information that will be disclosed must be relevant and proportionate, and highlights the need for it to be adequate on aspects that are more likely to materialize the main risks of serious effects, or on those aspects on which said risks have already materialized. We therefore consider that the Directive 2014/95/EU, on the one hand, highlights the transparency of the information and, on the other hand, that it is relevant and proportionate, so that it implicitly highlights the materiality of the information.

In this sense, there have been a number of studies (Jain, 2001; Svensson, 2005; Galang, 2012) that focus on how companies disclosing information related to corruption issues that are highlighted in the Directive 2014/95/EU. Disclosing information on how firms work in anti-corruption has been considered a prevention tool of bribery, extortion, accounting fraud, conflict of interest and so on (Rose-Ackermann & Palifka, 2016).

According to the above arguments, the main issue of our work is to verify the degree of disclosure of information about corruption and bribery presented by the listed companies on the Eurostoxx50 stock index. The rest of the paper proceeds in the following ways. In next section, we discuss the disclosure of non-financial information on corporate social responsibility: corruption perspective. We next talk about the directive 2014/95/EU and we then present our methodology. Finally, we end by providing conclusions.

Disclosure of non-financial information on corporate social responsibility: Corruption perspective.

Stakeholders give more importance to non-financial information. Nowadays, there is no doubt about the need for organizations to offer to their stakeholders' information about the impacts that their activity provokes from the social and environmental point of view, in aspects such as intellectual, human and social capital, corporate governance, environment and diversity policies and the fight against corruption and bribery.

In an investigation carried out by Brown and Deegan (1998), it was demonstrated that there is an increase in the disclosure of environmental information by companies. In this line, Patten (1992) argued that the increase in the disclosure occurred, namely in petrol organizations, because companies wanted to increase the organization reliability. In accordance with the foregoing, we understand that the disclosure of social and environmental information is an attempt by organizations to legitimize its actions with its stakeholders (Roberts, 1992; Blackburn et al., 1994; Moneva & Llena, 1996).

According to the above arguments, organizations attend to the expectations of the stakeholders, therefore, it will be beneficial for their survival in the long term. The aforementioned links with the theory of stakeholders, according to which "the essential mission of management is to conveniently satisfy the different groups of stakeholders, in order to achieve an adequate return and an acceptable increase in wealth for the company to medium and long term" (Lorca, 2003). For this, the organizations organize its resources in such a way that it can satisfy the diversity of their stakeholders (Donaldson & Preston, 1995; Pava & Krausz, 1997).

Henceforth, stakeholder theory responds to a series of fundamentals such as (Näsi, 1995; Freeman & Harrison, 1999; Freeman et al., 2010; Parmar et al., 2010):

- Organizations depend on the relationships between their stakeholders, being affected and affecting in turn.
- Organizations exist due to the interactions, transactions and exchanges carried out with stakeholders, studying this theory the origin of these relationships, understood as processes and their results (Piñera et al., 2000).
- The stakeholders' interests and objectives have an intrinsic value, highlighting that none is more important than another one.
- Conflicts of interest may arise between stakeholders that make up the organizations.

According to these aspects, organizations are aware of this trend, and currently, are addressing the disclosure of what is known with the term non-financial information. Despite the advances in this regard, we are still in the homogenization phase. Until the publication of the European Directive on non-financial information, of November 2014, companies had no obligation to disclose this type of information.

In the business environment and once organizations have been convinced of the need and importance of devoting resources to the preparation of the CSR report, large companies adopted more or less quickly international initiatives in this area. Despite the fact that information on corporate social responsibility lacks some sufficiently objective and standardized measurement systems that provide comparable and rigorous non-financial information (Lizano, 2013), some works related to the Global Reporting Initiative (GRI) have been carried out in recent years. In this line, we should highlight some legal norms, such as in South Africa, some precursor works such as those carried out in the United States at the end of the 20th century, and the beginning of the 21st: Jenkins and Enhanced Business Reports (Flores, Lizcano, Mora, & Rejón, 2012b). In this regard, we may say that the voluntary nature of Corporate Social Responsibility and, therefore, of the issuance of reports on these aspects, is being dissolved by new normative additions such as the aforementioned European Directive. All of this aspects marks a milestone in the obligation of non-financial information.

In light of the above arguments, this study focuses on studying the corruption disclosure as part of non-financial reporting into annual accounts. In this sense, we argue that corruption is a phenomenon that covers a broad range of acts such as bribery, extortion, accounting fraud, conflict of interest and so on (Rose-Ackermann & Palifka, 2016). Especially, corporate reporting on corruption efforts is an instrument of prevention because, firstly, it guides organizations to adopt measure and to ensure their effectiveness (Hess, 2009), secondly, it contributes to increase the awareness of this problem among stakeholders. In this line, on one hand, there have been a number of studies that try to identify, corruptions' determinants and consequences for society and firms (Jain, 2001; Svensson, 2005; Galang, 2012), and, on the other hand, we should highlight international institutions and initiatives fighting of corruption, such as, World Bank, International Monetary Fund, Organization of Economic Cooperation and Development, United Nations and so on. Corruption disclosure is included in corporate social responsibility report, Global Reporting Initiative guidelines, United Nations Global Compact reporting and, since the publication of the Directive 2014/95/ EU, it should be published in a non-financial information section in the Annual Report. In the next section, we are going to talk about the Directive 2014/95/ EU.

Statement of non-financial information related to Directive 2014/95/EU

Directive 2014/95/ EU of the European Parliament and of the Council, of October 22, 2014, supposes the modification of the Directive 2013/34/EU of June 26, on the consolidated financial statements and other related reports of certain types of organizations. This directive deals with the disclosure of non-financial information and information on diversity by certain large companies and certain groups. As a starting point, this directive establishes that certain companies, by size or public interest should publish in their management reports or in independent reports, from 2017, their impacts on social, environmental, diversity policies, respect for human rights and measures against corruption and bribery (TECNISA, 2015).

Firstly, article 19 bis, which is called Non-Financial State, is inserted in chapter 5, on Management Report. Namely, it is determined that large companies that are entities of public interest (see note 2) that, on their balance sheet closing dates exceed the criterion of an average number of employees over 500 during the year will include in the management report a non-financial state related to environmental, social issues and the fight against corruption and bribery.

Secondly, article 20 is modified, in relation to the Declaration on Corporate Governance, which requires the incorporation of a description of the diversity policy applied to the administrative, management and supervision bodies of the company, on issues such as age, gender, training and professional experience. If a policy of this type is not applied, organizations must offer an explanation about it.

Thirdly, another of the amendments included in this Directive is related to the information of the payments made to public administrations, which were already contemplated in the previous Directive. In this case, the European Commission must consider in a report- that has to prepare before the July 21, 2018- the possibility of introducing an obligation for large companies to submit annually, a report by country for each member state and third country in which operates, at least, the benefits obtained, taxes on benefits paid and the public subsidies received.

Fourthly, it is also necessary to inform about the way to apply the modifications established in the analyzed Directive to the consolidated reports, as well as the responsibility of the administrative, direction and supervision bodies of the companies on the writing, publication of the financial reports and non-financial aspects of the company, in accordance with the applicable regulations.

Lastly, and with regard to modifications, article 29 bis is inserted, in relation to the consolidated non-financial statement, which is identical to 19 bis, but for the groups of companies.

In relation to matters related to the fight against corruption and bribery, which is the main objective to be addressed in this investigation, the directive 2014/95/EU argues that organizations should disclose material information about how to manage anti-corruption and bribery cases. For this reason, organizations may disclose information on decision and management instruments and on resources allocated to the fight against corruption and bribery. At the same time, organizations explain how they evaluate the fight against corruption and bribery and the measures that they adopt to prevent or mitigate adverse effects, monitor effectiveness and communicate the matter internally and externally. In this sense, organizations may disclose significant information and key performance indicators on aspects such as the following:

- Anti-corruption policies, procedures and standards;
- Criteria used in corruption-related risk assessments;
- Internal control processes and resources allocated to preventing corruption and bribery;
- Employees having received appropriate training;
- Use of whistleblowing mechanisms;
- The number of pending or completed legal actions on anti-competitive behavior.

The transposition of this Directive to the member states should be carried out before the end of 2016, and the contemplated provisions should be applied by the companies as of the fiscal year that began on January 1, 2017. Finally, all the member states have made the aforementioned transposition, and in the matter that concerns us all countries incorporate the need to report on corruption and bribery .

Methodology

Sample and time period

To carry out this work, we have chosen the companies that are listed on the Eurostoxx50, for the year 2017. The Eurostoxx 50 index was presented in partnership on February 26, 1998. Its birth is related to the definitive formation of the European Union and the establishment of a single currency, the Euro.

In this sense, in table 1, our sample is presented by country and industry. In panel A, figures show that the industry with highest representation in our sample is technology and telecommunications and the lowest is consumer services. According to the country, the countries with more representation in our sample are France and Germany and the lowest Finland and England.

Table 1: Sample selection and analysis

Panel A: Composition of the sample firms according to the industry type	N	%
Oil and energy	7	14
Basic materials, manufacturing and construction	5	10
Consumer goods	11	22
Consumer services	4	8
Technology and telecommunications	12	26
Financial services and insurance	10	20
Total	50	100
Panel B: Composition of the sample firms according to the country	N	%
Spain	5	10
Netherlands	6	12
Germany	15	30
Finland	1	2
France	18	36
England	1	2
Italy	3	8
Total	50	100

The choice of this sample is due to the fact that since the objective of our work is to analyze the degree to which companies are complying with the requirements imposed by the community directive, we understand that a significant sample will be represented by European companies, since we are referring to a European regulation. Nowadays, all European Union countries have incorporated this disposition into their national regulations, so the reports referring to 2017 should comply with the requirements set out on it.

CSR disclosure index

A disclosure index of particular information has been used in numerous research which analyze company reports. An index of disclosure shows the level of disclosure in a set of company in which they compliance with regulations (Marston & Shrives, 1991). In this investigation, we have carried out an index of disclosure which includes a mixture of items required by regulation and voluntary about corruption and bribery of the Eurostoxx 50 companies. In this regard, we have started from the base information that according to the guidelines should be included in the non-financial information report, and the European Union countries have incorporated into their national regulations. Subsequently, each of the main points have been divided into different items on corruption and bribery that are already foreseen in standards generally accepted and contrasted by some interest groups, such as the GRI, the Global Compact or the OCDE Guidelines.

For these purposes, each category was assigned a score according to the amount of information that is included in the annual report. In this study, what we intend to measure is the amount of information disclosed by the company (Wallace et al., 1994; Giner, 1997), so we give the following score: 1 if full information is provided; 0 if information is not provided; and 0.5 if partial information is provided. In order to locate the required information, we have used the analysis of the contents of the annual reports presented in the year 2017 by the listed companies on the Eurostoxx 50. In this regard,

we have checked in the non-financial report or sustainability report within its annual report information related to the corruption and bribery (see table 2). According to the Directive 2014/95/EU, one of the models that can be used to provide non-financial information is the GRI. For this reason, for the development of the factors that make up table 2, we have taken the information related corruption and bribery that companies have to disclose following what is established in both the G4 and the standard 205 from the GRI.

Table 2. Corruption and bribery information

There is a non-financial section into the annual report or sustainability report	
Anti-corruption policies, procedures and standards	Report the anti-corruption policies, procedures and standards
	Reports on the managerial position responsible for this issue
Criteria used in corruption-related risk assessments	Report the total number and percentage of operations assessed for risks related to corruption
	Report the significant risks related to corruption identified through the risk assessment
Internal control processes and resources allocated to preventing corruption and bribery	Report the internal and external mechanisms for reporting concerns about unethical or unlawful behavior, and matters related to organizational integrity, such as escalation through line management, whistleblowing mechanisms or hotlines
	Reports on the managerial position responsible for this issue
Employees having received appropriate training	Report the total number and percentage of employees that have received training on anti-corruption, broken down by employee category and region.
	Report that employees have received training on anti-corruption, broken down by employee category and region.
Use of whistleblowing mechanisms	Report the use of whistleblowing mechanisms
	Report the possibility of making complaints anonymously
	Report on the degree of satisfaction of the users of the irregularity reporting mechanisms
The number of pending or completed legal actions on anticompetitive behavior	Report the total number and nature of confirmed incidents of corruption
	Report the total number of confirmed incidents in which employees were dismissed or disciplined for corruption
	Report public legal cases regarding corruption brought against the organization or its employees during the reporting period and the outcomes of such cases.

According to Muttakin and Khan (2014) the corruption and bribery disclosure index has been calculated as follows:

$$CBDj \text{ index} = (\sum_{i=1}^n (t_i)^{nj} \cdot X_{ij}) / nj$$

Where: CBDj index is the corruption and bribery disclosure index for j firms; nj is the numbers of items expected for j firms, where $n \leq 14$; and X is 1 if full information is provided, 0 if information is not provided, and 0.5 if partial information is provided, so that $0 \leq CBDj \text{ index} \leq 1$.

Empirical results and discussion

In this section, we report the factor analysis, descriptive statistics and correlation matrix.

In table 3, we highlight that the factors of the corruption and bribery index have a p-value smaller than 0.05. It means that we can accept the null hypothesis which argues that our factors are suitable.

Table 3. Factors of the corruption and bribery index

Factors of the corruption and bribery index	Bartlett test	
	Chi-square	Sig.
Anti-corruption factor	3.437	0.050
Risk related to corruption factor	5.814	0.016
Internal and external mechanism factor	11.570	0.001
Training factor	7.600	0.006
Whistleblowing factor	46.325	0.000
Completed legal factor	85.434	0.000

The Table 4 and 5 show descriptive statistics on corruption and bribery information, such as mean, standard deviation, minimum and maximum, for the studied corruption and bribery disclosure index. In this regard, as indicated in table 4, the figures present that only 59.2% of our sample publishes a non-financial section in the annual accounts and 46,9% of our sample says that firms present information related to corruption and bribery into the financial statements or sustainability report. Thus, the listed firms from the Eurostoxx 50 are still missing the corruption and bribery disclosure in the respective non-financial section.

Table 4. Descriptive Statistic about corruption and bribery disclosure I

Variable	Obs	Mean	Std. Dev.	Min	Max
There is a non-financial section	50	0.592	0.497	0	1
There is corruption and bribery information into the financial statements	50	0.469	0.504	0	1
There is corruption and bribery information into the sustainability report	50	0.469	0.504	0	1
There is corruption and bribery information into others parts of the annual accounts	50	0.561	0.496	0	1

Table 5 shows the corruption and bribery disclosures about our firm sample. In this vein, figures present that the aspects which are more disclosed to follow the next order: the anti-corruption policies, procedures and standards with a mean of 64.3%; internal and external mechanisms for reporting concerns about unethical or unlawful behavior, and matters related to organizational integrity with a mean of 58.7%; criteria used in corruption-related risk assessments with a mean of 54.1%; use of whistleblowing mechanisms with a mean of 51%; employees have received training on anti-corruption with a mean of 46%; and number of pending or completed legal actions on

anticompetitive behavior with a mean of 26%. Finally, the mean scores for the total index shows a corruption and bribery disclosure of 48.6%. Thus, we highlight that our firm sample should keep focusing on corruption and bribery disclosure because it has some aspects where is still having some lack information.

Table 5. Descriptive Statistic about corruption and bribery disclosure II

Variable	Obs	Mean	Std. Dev.	Min	Max
Anti-corruption factor	50	0.643	0.306	0	1
Anti-corruption policies	50	0.867	0.285	0	1
Anti-corruption policy officer	50	0.418	0.472	0	1
Risk related to corruption factor	50	0.541	0.358	0	1
Quantification of risks related to corruption	50	0.367	0.454	0	1
Description of risks related to corruption	50	0.714	0.421	0	1
Internal and external mechanism factor	50	0.587	0.366	0	1
Internal and external mechanisms to preventing corruption and bribery	50	0.745	0.410	0	1
Internal and external mechanism officer	50	0.429	0.445	0	1
Training factor	50	0.469	0.374	0	1
Number of training employees	50	0.265	0.434	0	1
Training employees	50	0.673	0.463	0	1
Whistleblowing factor	50	0.510	0.320	0	1
Whistleblowing mechanisms	50	0.745	0.410	0	1
Anonymously whistleblowing mechanisms	50	0.622	0.484	0	1
Satisfaction whistleblowing mechanisms	50	0.163	0.344	0	1

Variable	Obs	Mean	Std. Dev.	Min	Max
Completed legal factor	50	0.265	0.373	0	1
Number of incidents of corruption	50	0.388	0.482	0	1
Number of incidents in which employees were dismissed	50	0.214	0.395	0	1
Number of corruption public legal cases (pending or completed legal actions)	50	0.194	0.379	0	1
Size	50	11,623	1,342	9,417	14,489
Index of disclosure	50	0.486	0.238	0	0.93

Table 6 presents the correlation matrix among the factors that compose the disclosure index and other variables such as size, country and industry. As Table 6 indicated, the correlations among the variables show that anticorruption factor has a positive and significant relationship between risk related to corruption, internal and external mechanism and whistleblowing factors. Risk related to corruption factor has a positive and significant relationship between internal and external mechanism, training, whistleblowing and completed legal factors. Internal and external mechanism factor has a positive and significant relationship with training and whistleblowing factors. Training factor has a positive and significant relationship with whistleblowing factor. And whistleblowing factor has a positive and significant relationship with completed legal factor.

Table 6. Correlation matrix

	CBDI	Anti-corruption factor	Risk related to corruption factor	Internal and external mechanism factor	Training factor	Whistleblowing factor	Completed legal factor	Size	Country	Industry
CBDI	1									
Anti-corruption factor	,578**	1								
Risk related to corruption factor	,666**	,373**	1							
Internal and external mechanism factor	,751**	,526**	,498**	1						
Training factor	,630**	,255	,379**	,457**	1					
Whistleblowing factor	,799**	,366**	,314*	,570**	,388**	1				
Completed legal factor	,644**	,110	,294*	,184	,197	,492**	1			
Size	,084	-,049	,065	-,012	,130	,151	,027	1		
Country	-,103	,237	-,063	-,167	,015	-,238	-,094	-,074	1	
Industry	-,065	-,189	,131	-,045	,087	-,009	-,194	,421**	,016	1

In table 7, we can see a crosstab between the level of corruption and bribery disclosure and the industry. The figures present that the industries that disclose more information about corruption and bribery are some from technology and telecommunications and financial services and insurance. But we should highlight that their level of corruption and bribery disclosure is about 51% and 75%.

Table 7. Relationship between the level of corruption and bribery disclosure and industry

		Level of corruption and bribery disclosure				Total
		Between 0 and 25%	Between 26% and 50%	Between 51% and 75%	Between 76% and 100%	
Industry	Oil and energy	2	0	4	1	7
	Basic materials, manufacturing and construction	1	1	0	3	5
	Consumer goods	5	1	4	1	11
	Consumer services	0	2	2	0	4
	Technology and telecommunications	3	1	8	0	12
	Financial services and insurance	0	3	6	1	10
Total		11	8	24	6	49

Furthermore, in table 8, there is a crosstab with the relationship between the level of corruption and bribery disclosure and country. In this case, table presents that the countries with more level of corruption and bribery disclosure in our sample are France and Germany disclosing a level of 51% and 75% of information.

Table 8. Relationship between the level of corruption and bribery disclosure and country

		Level of corruption and bribery disclosure				Total
		Between 0 and 25%	Between 26% and 50%	Between 51% and 75%	Between 76% and 100%	
Country	Germany	4	2	7	2	15
	Spain	0	0	4	1	5
	Finland	1	0	0	0	1
	France	3	4	9	2	18
	England	1	0	0	0	1
	Italy	0	0	2	1	3
	Netherlands	2	2	2	0	6
Total		11	8	24	6	49

Conclusions

This investigation examines the degree of disclosure of information about corruption and bribery presented by the listed companies on the Eurostoxx50 in 2017, year in which the European companies have to publish a mandatory non-financial information. Specifically, we analyze the corruption and bribery matters included in the annual accounts by a sample of 50 European listed companies that were affected by the new EU-legislation.

In this sense, we statistically verify the level of corruption and bribery disclosure showing that around sixty percent of our firm sample was disclosing non-financial information in the mandatory section that the Directive 2014/95/EU argues. Furthermore, we find that the corruption and bribery aspects more disclosed are related to the anti-corruption policies, procedures and standards; internal and external control processes and resources allocated to preventing corruption and bribery; and criteria used in corruption related to risk assessments. On the other hand, we highlight that training on anti-corruption that employees have received and the number of pending or completed legal actions on anticompetitive behavior are the less disclosed aspects. Our findings also show that the industries that disclose more information about corruption and bribery are technology and telecommunications and financial services and insurance. Finally, the countries that present the highest levels of disclosing are France and Germany.

Overall, this work provides insights about the behavior that Eurostoxx50 firms have done during the implementation of the Directive 2014/95/EU in the year where European firms have had to publish non-financial information in a specifically section. In this sense, our findings have public policy implications because they suggest that firm are responding to the disclosure of corruption and bribery information. However, we should point out that there is still a long way to get disclosure about corruption and bribery from all companies.

This investigation shows a first step in studying the evolution of disclosure aspects related to corruption and bribery under the Directive 2014/95/EU. In this line, we should highlight that this work also has several limitations: firstly, we have examined only a limited sample of European listed companies during on year. For this reason, this work should extend the sample and the time period in order to corroborate our results. Secondly, another limitation is focused on the idea that scoring model represents a non-objective evaluation of the quality of information. Additionally, further investigations could be focused on analyzing what factors affect or impact on the level of disclosing.

Abstract. *The paper presents the findings of a survey based study investigating predictors of socially conscious consumption in Romania, a European country confronted with many societal issues, whose citizens were found to be highly concerned about some of the environmental problems, but less aware about some important others. The paper presents in brief the Romanian context and the theoretical background, focusing on the role of socially conscious consumers and the literature explaining the importance of cultivating pro-social behaviors, as necessary ingredients towards sustainability. Data collection and statistical analysis are detailed, discussing the findings and research limitations, as well as potential directions for the future studies. In line with previous literature, the present study finds the positive influences of education and civic engagement on socially responsible consumption behavior. Results indicate education as a highly relevant demographic characteristic in predicting consumer's responsibility. The paper emphasizes the need of investment in Romanian education, and the multiple benefits Romania would gain by narrowing the gap in this important area, but not only.*

Keywords: *Socially conscious consumption; social responsibility; civic engagement; education, Romania.*

Introduction

Civic life of modern consumers is subject of intense academic education and research debate. Social implications of consumption are scrutinized and non-material needs, such as civic participation, are analyzed (Briceno & Stagl, 2006), because consumption habits and patterns are one of the main causes for serious environmental problems, and not only. Developed and even emergent societies are increasingly worried that present consumer culture, stimulating excessive and selfish consumption, negatively influences societal values and civic engagement, hurting social cohesion and integration, as well as long term sustainable development. As a consequence, social responsible behaviors, consumer citizenship, socially conscious consumerism and relationships between various types of responsible consumption and civic engagement have been thoroughly investigated (Antil, 1984; McGregor, 2002; Keum et al., 2004; Briceno & Stagl, 2006; Cotte, 2009; Atkinson, 2011; Bocken et al., 2014; Cho, Keum & Shah, 2015; Chang, 2017; Crișan, Zbucnea & Moraru, 2017).

Consumerism is more and more criticized for the negative influences on various social goods, such as civic values and social connection (Atkinson, 2011). There are, however, newly developed trends towards a so called socially conscious consumption, or responsible consumption. Consumer responsible behaviors and civic minded consumers can change the way companies operate on markets, to incorporate societal interests and ensure greater sustainability. Pro-social consumer orientations are cultivated, because they can positively influence civic engagement and sustainability. Such efforts result in support for social responsible companies (Bocken et al., 2014; Andrei et al., 2017), despite of the fact that socially responsible consumers are not always willing to pay a premium price for the products sold by CSR involved companies, and serious gaps exist between stated intentions and real behaviors (Cotte, 2009; Bradu & Zait, 2016; Chang, 2017; Zbucnea, 2013).

Recent studies indicated that consumers not only undertake socially responsible actions in support of those companies they perceive as honest players in the market (Andrei et al., 2017, but they also manifest the willingness to become activists and fight against big societal issues (i.e. pollution, depletion of natural resources, loss of biodiversity, unethical business practices and so on), as Chang (2017) emphasized. In this way, they develop a civic conscience and become better citizens, involved and active (Zait, 2017), some authors indicating a growing number of those adopting socially responsible behaviors across the world (Cotte, 2009).

However, defining and describing the social conscious consumer is not an easy task, since many studies discovered that the most common descriptors used in consumer research – both demographics and psychographics – often lead to contradictory results and suggest that more personality variables and values should be considered for better explanations. To make things even more provocative, nowadays democratic societies struggle for cohesion and integration through diversity and pluralism, allocating even more weight to civic minded behaviors and community feelings, civic engagement being sometimes the only one holding a pluralistic society together (Bertelsmann, 2003).

Therefore, environment and society interests are more and more valued, by both companies and consumers (Crane, Matten, & Moon, 2008), and we are witnessing an increase in the levels of civic participation but a simultaneous growth of consumption of all types: both socially conscious consumption, and status oriented, selfish consumption. This reality indicates the need of investigating the connections between the level of civic participation and the type of consumption behavior a person adopts: socially conscious or status-oriented consumption. We remind here that socially conscious consumption refers to a buying behavior that benefits society as a whole, consumers being aware of the public consequences of their purchasing actions, while status-oriented consumption involves purchasing of products that reveal an individual's social position, heavily materialistic (Cho, Keum & Shah, 2015).

Research assumptions

Considering described context, our study was designed to diagnose the relationships between socially responsible consumption behavior and civic engagement in Romania. an EU country from East-Central Europe zone, confronted with many societal issues, whose citizens were found to worry less than other Europeans about the negative impact of consumption habits, but to be highly concerned about environmental issues

such as air pollution, as Luca et al. (2018) indicated in a study discussing the main environmental concerns in European Union. Highlighting that 60% of Romanians are worried about air pollution (comparing to 56% at EU-28 level), water pollution (45% of Romanians, comparing to 50% at EU-28 level), the growing waste (37% of Romanians, comparing to 43% at EU-28 level), health impact of the chemicals which are used in consumer goods (33% of Romanians, comparing to 43% at EU-28 level), and the depletion of natural resources (24% of Romanians, comparing to 36% at EU-28 level), Luca et al.(2018) reported consumption habits among top 10 environmental concerns of Europeans. Their study has found that almost a quarter (24%) of EU-28 citizens are worried about the negative impact of consumption habits, while slightly lower concerns on this issue (18%) were found among people from East-Central Europe zone which includes Romania, as well as Bulgaria, Croatia, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, Slovenia (see details in Figure 1).

Figure 1. Main environmental concerns in EU28 and East-Central Europe (Luca et al., 2018, p.5)

Given the aforementioned considerations, the study hypothesized that:

H: Civic engagement exerts a positive influence on socially responsible consumption behavior.

The research tested assumed relationship on a Romanian sample, taking also into account the potential influences which might appear due to participant's characteristics such as: education level, family income, work experience, age, gender, urban or rural area of provenience.

Method, measurement and data collection

A survey study was conducted to explore responsible consumption phenomenon in Romania, using an online questionnaire applied with 259 participants (64.9% female, ages 19-30, Romanian nationality students enrolled in the academic year 2016-2017 at

undergraduate (62.5%), master (33.3%) or doctoral studies (4.2%) in Bucharest or Iasi - two of the largest university centers of the country).

Applied questionnaire collected data on 41 items (detailed in Table 1) measuring on 5 points Likert scale (1= not at all; 5 = very much) the level of person's engagement in civic actions (1 item denoting civic engagement dimension: *"I have often participated in activities such as volunteering, environmental protection actions, community support actions, social projects of non-governmental organizations"*), and socially responsible consumption behavior (40 items comprised in SRCB scale advanced by Antil,1984; Antil & Bennett,1979), plus participant's demographic data (8 traits: education level, family income, work experience, age, gender, urban or rural area of provenience, county, nationality).

The questionnaire was applied in the local language, after a translation and back translation process employed to ensure cultural adaptation of the 40 items of SRCB scale (Antil, 1984; Antil & Bennett, 1979).

The sum-scores of participant's ratings on the 40 SRCB items (detailed in Table1 according to original scale of Antil, 1984; Antil & Bennett, 1979) were computed into the variable '*socially responsible consumption behavior*', which was further used in the statistical analysis.

SPSS software package was used to perform data analysis.

**Table1. Socially responsible consumption behavior
(SRCB scale of Antil, 1984; Antil & Bennett, 1979)**

Items
1. People should be more concerned about reducing or limiting the noise in our society.
2. Every person should stop increasing their consumption of products so that our resources will last longer.
*3. The benefits of modern consumption are more important than the pollution which results from their production and use.
4. Pollution is presently one of the most critical problems facing this nation.
5. I don't think we are doing enough to encourage manufacturers to use recyclable packages.
6. I think we are just not doing enough to save scarce natural resources from being used up.
7. Natural resources must be preserved even if people must do without some products.
8. All consumers should be interested in the environmental consequences of the products they purchase.
*9. Pollution is not personally affecting my life.
10. Consumers should be made to pay higher prices for products which pollute the environment.
11. It genuinely infuriates me to think that the government does not do more to help control pollution of the environment.
12. Non-returnable bottles and cans for soft drinks and beer should be banned by law.
13. I would be willing to sign a petition or demonstrate for an environmental cause.
14. I have often thought that if we could just get by with a little less there would be more left for future generations.
15. The government should subsidize research on technology for recycling waste products.
16. I'd be willing to ride a bicycle or take a bus to work in order to reduce air pollution.
*17. I would probably never join a club or group which is solely concerned with ecological issues.

Items

- *18. I feel people worry too much about pesticides on food products.
- *19. The whole pollution issue has never upset me too much since I feel it's somewhat overrated.
- 20. I would donate a day's salary to a foundation to help improve the environment.
- 21. I would be willing to have my laundry less white or bright in order to ensure that I was using a nonpolluting laundry product.
- 22. Manufacturers should be forced to use recycled materials in their manufacturing.
- 23. I think that a person should urge his/her friends not to use products that pollute or harm the environment.
- 24. Commercial advertising should be forced to mention the ecological disadvantages of products.
- *25. Much more fuss is being made about air and water pollution than is really justified.
- 26. The government should provide each citizen with a list of agencies and organizations to which citizens could report grievances concerning pollution.
- 27. I would be willing to pay a 5% increase in my taxes to support greater governmental control of pollution.
- *28. Trying to control water pollution is more trouble than it is worth.
- 29. I become incensed when I think about the harm being done to plant and animal life by pollution.
- 30. People should urge their friends to limit their use of products made from scarce resources.
- 31. I would be willing to pay 10 RON more each month for electricity if it meant cleaner air.
- 32. It would be wise for the government to devote much more money toward supporting a strong conservation program.
- 33. I would be willing to accept an increase in my family's total expense of 120 RON- to promote the wise use of natural resources.
- 34. Products which during their manufacturing or use pollute the environment should be heavily taxed by the government.
- *35. People should be willing to accept smog in exchange for the convenience of automobiles.
- 36. When I think of ways industries are polluting the environment I get frustrated and angry.
- 37. Our public schools should require all students to take a course dealing with environmental and conservation problems.
- 38. I would be willing to stop buying products from companies guilty of polluting the environment even though it might be inconvenient.
- 39. I'd be willing to make personal sacrifices for the sake of slowing down pollution even though the immediate results may not seem significant.
- *40. I rarely ever worry about the effects of smog on myself and my family.

Note: *Denotes items that are reverse coded.

Data analysis and results

Descriptive analysis indicated the following structure of the sample: N=256 participants of Romanian nationality, 64.9% female, ages 19-30, undergraduate (62.5%), master (33.3%) and doctoral (4.2%) students, with an approximate family income per member under 2000 RON (68.7%), or over 2000 RON (31.3%), most of them (81,5 %) having a

little working experience or no experience, and only 18,5% reporting a consistent working experience.

Considering *socially responsible consumption behavior* as dependent variable, regression analysis was applied to test potential influences exerted on it by independent variables: *civic engagement*; *education*; *work experience*; *income per family member*; *age*; *gender*.

Statistical results (details in Table 2 and Table 3) indicated that two of the six independent variables considered, namely *civic engagement* and *education*, predict dependent variable *responsible consumption behavior* ($F = 63.473$, $p < 0.05$), explaining 60,2 % of its variance ($R \text{ square} = 0.602$).

Regression analysis output detailed in Table 3, have shown that *socially responsible consumption behavior* is positively influenced by *education* ($\beta = 0.136$; $t = 2.967$; $p < 0.05$) and *civic engagement* ($\beta = 0.728$; $t = 16.931$; $p < 0.05$; research hypothesis confirms).

The other 4 variables included in the analysis (*age*, *gender*, *family income per member*, *work experience*) were found to have no significant influences on *socially responsible consumption behavior*, as it is indicated by β coefficients detailed in Table 3.

Table 2. Results of regression analysis. Model Summary and ANOVA^a

Income per family member	-3.522	2.176	-.075	-1.619	.107
a. Dependent Variable: Socially responsible consumption behavior					

Overall, the results obtained on the Romanian student sample indicate that person's level of education (in this case enrollment in undergraduate, master or doctoral studies) and person's engagement in civic actions have positive influences on person's socially responsible consumption behavior.

Conclusions and discussions

Analyzing the data collected from 259 students (ages 19-30) enrolled in Romanian universities (undergraduate students 62.5%, master students 33.3% and PhD students 4.2%) the present study offers insights regarding responsible consumption phenomenon in Romania. The study finds positive relationships between responsible consumption and civic engagement, respectively between responsible consumption and education, indicating a profile of socially conscious consumers among young and educated Romanians.

In line with previous literature (Bodur & Sarigöllü, 2005; Andrei et al., 2017), the results of the present study indicate that person's level of education (in this case participant's enrollment in undergraduate, master or doctoral studies) and person's engagement in civic actions have positive influences on the tendency of consuming responsible and committing into "a deliberate effort to acquire, use and dispose of products in manners minimizing negative consequences and maximizing positive ones on both environmental and social levels", as Ertz (2016, p.6) described socially responsible consumption behavior.

Although the literature acknowledges that the level of income (which is known to induce price sensitiveness), as well as work experience should influence responsible consumption decisions (Gandhi & Kaushik, 2016; Kai & Liang, 2016; Vătmănescu et al., 2017, 2018) the present study finds no influences on these directions. The lack of significant influences exerted on responsible consumption decisions by participant's income and work experience in the present study might be a limiting consequence of a student sample. In this vein we mention that only 18,5 % participants reported a consistent working experience. Also, the single item measurement of civic engagement ("I have often participated in activities such as volunteering, environmental protection actions, community support actions, social projects of non-governmental organizations") represent a second limitation. To overcome these limitations, future studies might consider one of the multi-item measurements of civic engagement indicated in the literature (Doolittle & Faul, 2013; Jugert et al., 2013; Zait et al., 2017), as well as a larger sample. comprising all population categories.

Finally, the findings regarding the positive impact of both education and civic engagement on socially conscious consumption indicate education as most relevant among demographics in predicting consumer's responsibility. The result highlights the need of investment in Romanian education and the benefits Romania would gain by narrowing the gap it actually has in this important area comparing to other EU-28 countries.

CHALLENGES IN PROJECT MANAGEMENT

SUCCESS CRITERIA AND CRITICAL SUCCESS FACTORS OF CRM PROJECTS IN TELECOMMUNICATION COMPANIES

Abstract. *The paper aims to fill in the gap of investigating the success criteria and the critical success factors of CRM projects completed in Hungarian telecommunication sector. It highlights the importance of CRM projects aligned with the organization strategy, and introduces, what are the most important success criteria of these projects and what factors have an influence on the successful realization of CRM projects. The paper first gives an overview of the strategic importance of projects and project management. Then project success criteria and factors are discussed. Customer Relationship Management is introduced in order to analyze its role in strategic decision making. In the empirical part of the paper CRM projects at Hungarian telecommunication companies and their information technology suppliers are analyzed. Telecommunication companies are leaders in introducing and applying CRM systems in Hungary. In order to identify project success criteria, and the key success factors of CRM projects, as well as the relationship between them, a questionnaire was developed. Project managers and team members, as well as representatives of stakeholders – suppliers, consultants - of CRM projects at these companies, were asked to fill out the questionnaire by evaluating the CRM project they have worked for or they have been involved in. Experience in agile project management, in innovation, and in CRM system introduction is the characteristic feature of the selected respondents. 90 experts were selected and asked to fill out the questionnaire. Quantitative analysis has been made by using a database of 62 respondents. The importance of the research is that no empirical survey has been made by focusing on success criteria and factors of CRM projects neither in global nor in Hungarian perspective. The Standish Group has been investigating software development projects by applying the project triangle as success criterion and reveals the most important success factors of these projects, however, it provides general information of software development projects but no special attention has been made to CRM projects (Standish Group, 1995-2015). The PMI's Pulse of the Profession survey series also provides useful knowledge of success factors and criteria of projects, but its investigation doesn't give IT- and CRM-related information (PMI, 2012-2018). Furthermore, Hungarian projects don't take part in these surveys' samples. This indicates how our research fills in the gap of investigating the success criteria and the critical success factors of CRM projects completed in Hungarian telecommunication sector*

Keywords: *sustainability; strategy, project; success; assessment tool.*

Introduction

Project management is one of the most dynamic fields of management science and practice. The main challenge of project management is not just how to complete projects successfully, but how these projects contribute to the successful realization of organizational strategic goals as well (Martens et al., 2018; Pinto, 2016; Blaskovics, 2016; Cserhádi & Szabó 2014; Artto et al., 2008).

Customer Relationship Management plays an important role in strategic project management given that CRM systems as an outcome of these projects perform a bridging function between the project owner organization and its customers (Steel et al., 2013). Customer Relationship Management refers to principles, guidelines, tools, and methods used in order to identify, attract and satisfy the organization's customers. It is very important to understand the needs and behavior of customers and respond to the shifts of the customer's desire (Chen & Popovich, 2003; Krasnikov et al., 2009; Peppers & Rogers, 2011). CRM projects aim to develop and introduce CRM systems in order to increase the customer orientation of the organization. According to the Nucleus Research Report (Nucleus Research Report, 2016) companies are increasing their investments in CRM applications because of 4 times higher ROI. And yet, at the same time, C5Insight research shows that CRM projects fail between 30-60% of the time and this low-level success rate hasn't been improving over the last decade (C5Insight Report, 2017).

Project and project management

The Project Management Institute defines a project as "a temporary endeavor undertaken to create a unique product, service, or result" (PMBOK, 2017, p.4). Turner's definition – "an endeavor in which human, material and financial resources are organized in a novel way, to undertake a unique scope of work, of given specification, within constraints of cost and time, so as to achieve beneficial change defined by qualitative and quantitative objectives" (Turner, 2000, p.2) – highlights the importance of realizing project goals on time and on budget. Kerzner represents the process-based view by defining a project as "any series of activities and tasks that have a specific objective to be completed within certain specifications" (Kerzner, 2017, p.2).

Project characteristics are as follows:

- Unique;
- complex, complicated, one-time process;
- has a specific objective to be completed;
- limited by budget, deadline, and quality (project triangle);
- consumes human and nonhuman resources (fitness);
- has defined start and end dates (temporary);
- the project is customer-focused (added value);
- aligned with the organizational strategic goals.

Based on the management definition of Griffin (2017), project management can be defined as a set of activities (including planning, decision-making, organizing, leading, and controlling) directed at a project's resources (human, financial, physical, and information) with the aim of achieving project goals in an efficient and effective manner.

Project success

Project success is widely studied and discussed the phenomenon of project management. While some success criteria and factors are common across different project types, there are unique criteria and factors applying only to specific projects (Cserhádi-Szabó, 2014).

Approaches to project success have changed continuously over the past couple of decades from definitions of success and critical success factors to a more strategic, holistic view (Judgev & Müller, 2005).

Project success criteria

There are several theories focusing on project success criteria. The most used approach highlights the importance of the “project triangle” (Turner & Cochrane, 1993; Agarwal & Rathod, 2006; Fortune & White, 2002; Judgev & Müller, 2005) according to which successful projects are completed on time, on a budget, with all features and functions as initially specified.

However, this conception does not fully evaluate project success, since examining these parameters indicates merely the direct contribution to profit, whereas it omits taking into account whether the project meets all the expectations of the project’s stakeholders (Turner, 2000). Each interest group involved in the project may have different and sometimes conflicting criteria for evaluating outputs of the project (Artto et al., 2008). By evaluation of project success not only project effectiveness, the fulfillment of project triangle, but also project efficiency, stakeholders’ interests need to be taken into account (Deák, 2017; Görög, 2013).

The distinction between the task and psychosocial related criteria reflect the importance of stakeholders’ satisfaction as well (Cserhádi & Szabó, 2014). Task-related aspects are mainly based on the project triangle, whereas psychosocial-related criteria include the satisfaction of customers and end users, as well as the opinion of other project stakeholders (Pinto & Pinto, 1991).

In our understanding project, success criteria can be grouped into three categories as Figure 1 indicates.

The first perspective represents the traditional view of project success. Meeting the project triangle (time, cost, qualitative and quantitative requirements) includes criteria that indicate how effectively the project has been completed.

The next perspective represents the satisfaction of the project owner. It shows to what extent the project meets the owner’s expectations. In some cases, these expectations can be exactly defined already at the beginning of the project life cycle, like in construction industry, meanwhile, in many other cases the expectations and requirements are changing and are being modified during the whole project life cycle, like in case of software development, service development or reorganization projects. Therefore, this perspective is about the subjective evaluation of project success through the lenses of the project owner. It reflects how efficiently the project has been completed.

Figure 1. Different perspectives of project success criteria

The satisfaction of other parties involved in the project can also play an important role in assessing project success. End users, suppliers, vendors, consultants, contractors, local residents, as well as project team members have to be taken into account when analyzing the project success from this perspective.

Meanwhile, the satisfaction level of project stakeholders can be measured on a selected scale like on a five-grade Likert scale, the project effectiveness relies on objective data as total cost, the duration of the project and on different parameters of the project outcome. Consequently, empirical studies that evaluate project success by using the project triangle as success criteria provide comparative results, the evaluation of project efficiency is limited to the selected project and doesn't enable to collate them.

Project success factors

Once the project success criteria are defined, it is important to analyze, how project requirements could be accomplished. The successful project realization is determined by project success factors (Lim & Mohamed, 1999). Early studies (Baker et al., 1988; Pinto & Slevin, 1988) concentrated on revealing factors influencing a project's success or failure. Further publications (Belassi & Tukel, 1996; Cooke-Davies, 2002; Lechler, 1997) tried to classify factors and create a consistent model of success factors.

Belassi and Tukel (1996) reviewed the project literature and grouped project success factors into four categories: factors related to the project; to the project manager and team; to the organization; and factors related to the external environment.

Lechler (1997) developed a model of project success factors by creating three main categories: context, participants and functions. Using this framework, Gemünden and Lechler (1997) carried out an empirical survey which resulted in identifying critical success factors as the qualities of top management and project team as well as the communication.

Cooke-Davies (2002) defined project success factors at three different levels: the success of project management activity, project success, and consistent project success. The project management activity's success depends on specifying responsibilities and competences, integrated performance rating and effective risk management. As far as project success is considered efficient supporter and process management are the most important factors, whereas in reaching consistent project success practice of portfolio and program management as well as organizational learning play an important role.

Customer Relationship Management (CRM)

Customer Relationship Management is defined as “process companies use to understand their customer groups and respond quickly—and at times, instantly—to shifting customer desires” (Rigby, 2015). In order to increase competitiveness, organizations have to scan their environment by systematically collecting, storing, analyzing and using information and knowledge. Rapid change in the environment, new customer expectations, new products and services of competitors, technological revolution are examples why CRM became strategically more important.

Importance and functions of CRM systems

Since 1993, Bain & Company has surveyed executives around the world regarding the management tools they use and how effectively those tools have performed. The results of the global survey show that CRM has become one of the most important strategic management tools executives use. The last survey revealed that Customer Relationship Management (CRM) is the most used management tool regarding the executives' preferences (Rigby & Bilodeau, 2015).

Chen and Popovich (2003) and Fickel (1999) stress that CRM technology application has a key role in linking the front office functions (sales, marketing) and back office functions (operation, logistics, HR, finance) with the “company's customer touch points” like Internet, e-mail, social media, stores, kiosks, call centers.

Chen and Popovich (2003), and Goldenberg (2000) point out that CRM is not only a kind of technology but rather a “cross-functional, customer-driven, technology-integrated business process management strategy that maximizes relationships and encompasses the entire organization” (Chan-Popovich, p.673).

CRM systems are integrated, data-driven solutions. CRM systems offer various functions to be used in strategic decision making. These functions may include but not limited to:

- contact management that allows to segment contacts into groups to organize them;
- sales and sales related functions that help organizations to acquire new customers and to improve the sales processes;
- reporting functions with dashboards where users can view statistics using customized reports and dashboards including real-time data updates and a platform that can be accessed from various portals;
- customizable user interface;
- sales analytics;
- sales force automation that allows automating certain aspects of sales including outgoing calls, follow-up campaigns and the organization of data for more effective campaigns;

- sales forecasting that helps organizations to know a benchmark by which they can determine whether their results are actually on par with their efforts;
- workflow and approvals;
- sales performance management;
- creation of test environment;
- third-party integrations;
- case management (selecthub, 2015).

All of the above features are supporting the interaction with customers, customer service activities, sales support activities, customer care activities as well as finance and operations with automated solutions resulting in the modernization of operation and processing bulk amount of data (microsoft.com, 2017).

Advantages of CRM systems

The implementation of modern CRM systems offers a wide range of benefits. CRM system functions significantly improve the efficiency of operation and foster the interaction with customers. One of the biggest advantages includes collaboration. Even in small organizations, the entire customer lifecycle is typically too complex to be managed effectively by one person, but the use of CRM platforms supports the management of these complex systems. Besides, it is important to highlight other benefits as data storage, analytical functions, and the visualization toolset. Increased accountability can be achieved by logged changes of every activity resulting in improved customer experience (Robles, 2015).

The role of CRM in Telecommunication

CRM systems aim to provide agile and dynamic solutions resulting in the most effective customer serving activities. According to Deloitte's assessment from 2017, there is a higher tendency in the past few years in the telecommunication industry of adopting CRM systems (Wigginton, 2017). The reason for the dramatic increase is behind their needs for an efficient way of working with good quality. It is a high priority for companies working in this industry to be as fast as they can in order to serve the customers' increasing needs. In addition to this, the product portfolios of telecommunication companies change even faster than the environment. They must align their processes to this accelerated speed of changes. It is not only important because of their aspirations of becoming the leader of the market, but to stay alive there.

Empirical study

The aim of the research

The study aims to fill in the gap of investigating the success criteria and the critical success factors of CRM projects completed in Hungarian telecommunication sector.

The main research questions are as follows:

- What does project success mean for CRM projects in Hungarian telecommunication sector? What are the success criteria of CRM projects based on which the success of CRM projects is evaluated?

- What are the key success factors that have a significant influence on the success of CRM projects in Hungarian telecommunication sector?
- What is the relationship between success factors and success criteria of CRM projects in Hungarian telecommunication sector?

Methodology

Telecommunication companies are leaders in introducing and applying CRM systems in Hungary. The three biggest telecommunication companies – Telekom, Telenor, and Vodafone -- and two of their partners, big-sized information technology suppliers – Virtusa and Amdocs - were selected.

CRM projects at these Hungarian telecommunication companies and two of their big-sized information technology suppliers were analyzed.

In order to identify project success criteria, and the key success factors of CRM projects, as well as the relationship between them, a questionnaire was developed. Project managers and team members, as well as representatives of stakeholders – suppliers, consultants - of CRM projects at these companies, were asked to fill out the questionnaire by evaluating the CRM project they have worked for or they have been involved in. Experience in agile project management, in innovation, and in CRM system introduction is the characteristic feature of the selected respondents. 90 experts were selected and asked to fill out the questionnaire. Quantitative analysis has been made by using a database of 62 respondents.

Besides, three personal interviews were carried out in order to validate the results of the quantitative survey as well as to get a deeper understanding of the relationship between success factors and criteria of CRM projects. The interview partners represent the key strategic areas of CRM projects: marketing, IT development and consulting:

- Telenor SOHO segment value manager represents the marketing perspective of CRM projects.
- Telekom Lead Solution Architect represents the IT development perspective of CRM projects.
- BCA Hungary Lead Consultant represents the consulting perspective of CRM projects.

Research results

In this chapter, the paper concentrates on success criteria and key success factors as well as the relationship between factors and criteria of CRM projects based on the quantitative survey. In the discussion part of the paper, we use the outcomes of the interviews with representatives of different stakeholders.

Success criteria of CRM projects

Respondents were asked to list and rank the criteria based on which the success of CRM projects are evaluated at their organizations. The questionnaire itemized the success factors as follows:

- Project completion on time
- Project completion on budget
- Project completion by meeting the qualitative and quantitative requirements
- Satisfaction of project owner

- Satisfaction of other parties involved

Respondents had to determine the importance of each of these success criteria on a five-grade Likert scale where “5” indicates a very important and “1” a non-important success criterion.

Figure 2 shows the importance of project success criteria based on their average values.

Figure 2. The importance of the success criteria of CRM projects based on their average values

According to the survey, the most important success criterion of CRM projects is the satisfaction of other parties involved, followed by the project completion by meeting the qualitative and quantitative requirements. Project completion on time and on a budget, as well as the satisfaction of owner organization play less important role in evaluating the success of CRM projects.

Success factors of CRM projects

Based on previous empirical surveys on project success factors, a long list of factors was created. Respondents had to evaluate all items according to the extent they have an effect on the success criteria of CRM projects. A 5-grade Likert scale was used where “5” indicates a very high and “1” indicates a very low extent of influence.

Satisfaction of other parties involved

Figure 3 shows what factors have an influence on the satisfaction of the other parties involved in the CRM projects.

Figure 3. The effect of success factors on the satisfaction of the other parties involved

According to the survey, the *easy use of IT solution* is the most important factor that influences the project success from the perspective of other parties involved. More than 80% of the respondents stated the highest level of influence of this success factor, followed by *user involvement* (77,4 %) and *effective, mutual communication* (61,3%).

Project completion by meeting the qualitative and quantitative requirements

Figure 4. The effect of success factors on project completion by meeting the qualitative and quantitative requirements

Regarding the project completion by meeting the qualitative and quantitative requirements, the most determining success factor is the *clear statement of project goals* as more than 77% of the respondents stated the highest level of influence of this factor. Not significantly differs from this high level of influence the role of *effective, mutual*

communication (74,2%), meanwhile, other factors have a medium level effect on the qualitative and quantitative requirements.

Project completion on time, on a budget, the satisfaction of the project owner

The following three figures illustrate what are the most determining factors of project completion on time, on a budget, and on the satisfaction of the project owner. Although these criteria have lower priority in evaluating project success of CRM projects, it may be beneficial to identify their effects.

Figure 5. The effect of success factors on project completion by keeping the deadline

Figure 6. The effect of success factors on project completion by keeping the budget

Figure 7. The effect of success factors on the satisfaction of the project owner

A clear statement of the project goals, as well as an up-to-date time schedule, are the decisive factors on keeping the deadline and the budget, while *competent and motivated project team members* appear as success factor of keeping the deadline and *providing proper resources* is a key success factor of keeping the budget. As far as the satisfaction of project owner concerns, *effective, mutual communication*, a *clear statement of the project goals* as well as the *easy use of IT solution* are the most decisive factors.

Table 1. gives an overview of the most important success factors of CRM projects at Hungarian telecommunication companies.

Table 1. Summary of the results regarding the effect of key success factors on project success criteria

No.	Satisfaction of other parties involved (4.26)	Project completion by meeting the qualitative and quantitative requirements (3.87)	Satisfaction of project owner (2.29)	Project completion on time (2.29)	Project completion on budget (2.23)
1	Easy use of IT solution	Clear statement of project goals	Effective, mutual communication	Clear statement of the project goals	Clear statement of the project goals
2	User involvement	Effective, mutual communication	Clear statement of project goals	Competent and motivated project team members	Providing proper resources
3	Effective, mutual communication	Competent and motivated project team members	Easy use of IT solution	Up-to-date time schedule	Up-to-date time schedule
4	Quality and method of CRM training programs	Up-to-date time schedule	User involvement	Providing proper resources	Performance of suppliers, contractors and consultants
5	Effective change management	Providing proper resources	Executive management support	Performance of suppliers, contractors and consultants	Easy use of IT solution

Discussion

As indicated in Figure 2, the evaluation of CRM projects' success is based primarily on the satisfaction of other parties involved. The most important stakeholder is the client who is, at the same time, the end-user of the project outcome. Projects must satisfy the needs of the client by fulfilling all the requirements it specifies. However, in many cases, the client is not able to define all the requirements of CRM projects already at the beginning of the project. This is why agile project management is spreading rapidly in ICT projects. Agile approach embraces change even in the development or execution phase of the project lifecycle. The project life cycle is divided into short-term development phases, for what project and product requirements are defined. At the end of each cycles, results are controlled, assessed and activities, requirements for the next cycle are determined. Given the time-frame and the budget, requirements are adjusted during the project life cycle. The latest issue of Chaos report by Standish Group (2015) revealed that the success rate of software development projects using agile project management is 3-times higher than of traditional waterfall projects. Taking into account that many CRM projects (and almost all in the sample) use agile project management, keeping the deadline and the budget are of less importance when evaluating project success of CRM projects.

Project success factors are those factors that determine the project success. In order to manage CRM projects successfully, we have to identify them properly.

The most important success criterion of the CRM projects is the satisfaction of other parties involved. This is why factors that influence on this criterion are considered to be key success factors of CRM projects. Easy use of IT solution, user involvement, and effective, mutual communication are on top of key success factors of CRM projects followed by factors such as a clear statement of project goals, competent and motivated project team members, up-to-date time schedule and providing proper resources.

This finding is on the one hand aligned with the results of the Chaos Report (Standish Group, 2015) where user involvement, clear business objectives, skilled resources are among the most important success factors of software development projects. On the other hand, our study reveals additional, sector-specific success factors as easy use of IT solution, effective, mutual communication and up-to-date time schedule. CRM projects involve new IT solutions and the success depends on how easily these CRM systems can be used. The nature of CRM projects requires effective, mutual communication among the development team, consultants, users and other groups of stakeholders like suppliers, marketing experts. Interviews revealed that in the case of CRM projects the time-to-market is the center of attention. For this reason, up-to-date time schedule has to be managed.

Furthermore, the interviews revealed that identifying the success factors and the relationship between factors and criteria is crucial because of the high level of complexity of CRM projects. Risks can be effectively managed only if concentrating on key project success factors. CRM projects' success or failure have an impact on organizational strategic goals. These facts highlight the relevance of our study.

Limitations and further research direction

The results show a comprehensive view of CRM projects at Hungarian telecommunication companies. The selected companies cover a great part of the Hungarian telecommunication sector. Respondents and the interview partners have demonstrated considerable experience in managing CRM projects. Despite all of these facts, there are many other companies in the Hungarian telecommunication industry dealing with CRM projects. Besides, the three biggest telecommunication companies have been applying well-established project management standards by using their international experiences; consequently, these results do not reflect the real Hungarian case. Further investigation should focus on CRM projects at small- and medium-sized enterprises in order to discover success factors and criteria of CRM projects at these companies that enables a comparative analysis by differentiating success factors and criteria by size and by organizational project management maturity.

CHANGES IN COOPERATION IN PROJECT MANAGEMENT

Elvira KUHN

University of Applied Sciences
Schneidershof, 54294 Trier, Germany
e.kuhn@hochschule-trier.de

Abstract. *Today, project management (PM) has to meet the requirements of customers' rapidly changing requirements, new opportunities arising from technical progress, the ideas of investors or the legal framework in ongoing development. Gone are the days of contracts with fixed targets. Problems are named and outlined. Changes in the approach to PM and the transfer of self-responsibility to teams through agile processes such as Scrum, eXtreme Programming, Crystal or Kanban have already been introduced 12 years ago. This already had serious effects in communication. Furthermore, the approach of the anti-fragility claims in addition to the ability to communicate co-operation, readiness and assumption of responsibility. In this paper, we focus our discussion on changes in PM on the antifragility approach and address the tasks to be tackled in the change process from the transition from agile to anti-fragile approaches. First of all, the question is which requirements are to be placed on these supporting instruments for PM and which boundary conditions must be taken into account. Are new success factors to be considered in the new PM? How do we deal with internationalization? How about virtual worlds? How about the demand for mobility? And what is the impact of increasing multicultural diversity? Are disadvantages of the previous PM minimized or are they completely eliminated? Do disadvantages have to be accepted? Which? Who are the winners in the use of our newly developed anti-fragile PM? Is it financeable? In order to answer these questions, we deal intensively with the evaluation of existing methods and techniques. Because of projects that are rated as critical - this so far concerned quality, legality, financing, time and benefits - require the special attention of top management our new recognized factors have to be included in the evaluation of a crisis to obtain a better benefit of a project.*

Keywords: *cooperation; antifragility; digitalization; mobility; virtual organization.*

Introduction

The main goals of a project management (PM) are to achieve results that consist of - partly changing customer requirements, but still keeping to planned costs, planned times, planned use of resources and employees. The project manager can sometimes be part of the company, sometimes outside the company. Sometimes he has a team of members of different companies - sometimes even from different countries - to lead. They all have a common problem to solve. Due to the rapidly changing requirements of customers, a contract with fixed goals is no longer possible. Too many new technical possibilities, new laws that allow expansion or reduce the planned chances, or new ideas of the addressed clientele influence the further development. To meet changing environments, agile PM addresses the flow of communication within teams, as well as the scope and responsibility of each team member (seen in Sutherland, 2015). To date, the manager has been tasked with organizing and controlling the use of new technologies, selecting standards and methods, coordinating interactions between colleagues or between colleagues and customers, in conjunction with the permanent,

fast - changing environment. The core idea of reducing the complexity of these challenges is to gradually divide up the entire project. Instead of following fixed plans, agile PM can act flexibly. Permanent changes are possible and accepted.

In this paper, we focus our discussion on changes from the planned via the agile to the anti-fragile approach. Essential in agile PM is the self- responsible work of team members in a decentral network with distributed responsibilities (Agile Manifest 2001).

A stable working environment and exact predictions for the continuation of the work are necessary in a plan-oriented PM, where first a work plan is set up. This one is very fragile. Therefore, the ongoing development of the project is subject to fluctuations and shocks. It's about surviving these situations. The goals of an anti-fragile approach are to have more advantages than disadvantages in stressful situations and to be profitable. Taleb (2012, pp.31-40) compares to the Hydra. The main question is: What do we have to change in agile PM to get an anti-fragile PM? To answer this question, we need to consider the process, methods, and capabilities of anti-fragile PM.

Methodology

The anti-fragile approach claims to be able to support a high co-operation, including readiness and assumption of self-responsibility of all team members. The question is: What is the right manner of cooperation and how the top management can support this?

Beforehand, we provide a brief overview of task management in PM in general, special features in multi-project management, agile features before we use this scheme to highlight the specific challenges of the anti-fragile approach in PM. Discussion elements of the organization are procedures in the project process, new tasks and new roles, and subsequently the adoption of outdated concepts. We examine the question of the needed methods, techniques, standards and IT-Support. The anchoring in the company from a corporate and strategic point of view is another point of discussion. This is intended to ensure the sustainability of a changed PM. Training concepts and further developments in the area of the anti-fragile approach must also be taken into account in order not to miss the connection to further changes. As last result we list the recognized factors which have to be taken into account in addition to financing, time and benefits to make sure that ultimately, motivation and creativity should all be maintained for a long time.

Our methodology is shown in the figure 1. We start with the discussion of tasks of different types of PM to highlight the specific challenges of a planned, agile and anti-fragile project approach, we compare the organizational possibilities to support the needed cooperation within the development of a project, we examine which tools are used to support cooperation, and we end summarizing our discussion within a short table which will content the difference between a planned, an agile and an anti-fragile PM taking into account boundary conditions.

At the end you will find out why the sole good communication flow with the view of time stamps and costs are not enough.

Figure 1. Methodology to show changes of PM

Tasks of PM

In this part of the paper, our goal is to figure out a scheme to highlight the specific challenges of the anti-fragile approach coming from a waterfall and an agile PM phase concept – as a process to develop products or services. In every PM the main tasks of a manager are, to plan, to decide, to coordinate and to control (as seen in Gabriel & Baier, 2003), but the tasks will be done in different phase dependent of the underlying process. In the case of PM for developing software a special subject, called Software Engineering, exist to develop specific methods and technics to make sure that the requirements of clients are right understand and the results will be done in given time and costs. The construction of a phase concept as well as each phase itself, and even each tasks within the phases following the questions first why, then what, and at last how. In this way the complexity of working on a problem is reduced. After each phase the top management can say stop or go, or they can introduce some changes. There exist more or less phases, dependent from the constellation of the type of PM, product's boundary conditions, of the team compilation and the organization. For example, in the case of software development, waterfall PM requires separation of the phase concept into phases such as phase requirement analyses (1), phase conception of the expert view (user) for the required functions (2), user interface (3) and data processing concept (4). In the case of the desire to buy software, you only need the whole phase (1), a small part of the phase (2) and sometimes, if you have the possibility to determine the user interface yourself, a small part of the tasks of phase (3). We believe that analyzing a chess point to find out the problems is always necessary before starting the project definition. In the project definition you start to work on the specifications, and you name the goals, and the associated problems. Using phase models, you need to create a timestamp plan and resources. As shown in Balzert (2008), there are different types of plan-oriented phase models such as waterfall model (linear or cyclic), V-model, prototype model (horizontal / vertical), evolution / incremental model, object-oriented model, or spiral model. They all have the same goals in the PM – minimize the costs, times, risks, management expenses or maximize quality. The great difference in the characteristic is solving the whole problems step by step or only an increment from begin to end. Sometimes you start with the basic system and then you develop the next part - like an evolution. If you will go fast to market, you will have developed some parts of the product in such way

that you can sell it. Sometimes you begin the next part before the other part is finished, and sometimes you can work parallel on parts of your new product.

In agile PM, this recognition is the basis for the development of a product. Here, the product owner describes the requirements, sets the priorities and estimates the effort. From this, he creates Blogs with deadlines, which he discusses with the so-called master. This master manages the development process. The team is urged to answer any problems that occur immediately. With Scrum there can be daily or weekly meetings that only last a short time. In a sprint of 2-4 months the team members can working on Blogs. At the daily meeting each team member is asked for the first time which problem he wants to solve and what he will do until the next time. At the 2nd - nth time there are always exactly 3 questions: were you done until today? There were problems? What are you going to do until next time? Here is no way to hide in a group. Everyone must answer for himself. If someone has had problems, he can say so openly. Everyone helps, so there is no delay in the whole project. First, the problems are resolved before it is allowed to proceed. An old slogan says: a chain is as strong as the weakest link. And who would like to pay for a project in which one person has done a wonderful job and another does not, so that the product cannot be sold?

Agile methods are focused on the result. Now, it may be that all team members belong to the enterprise. Then it is an internal project. But if the members are from different companies - as is generally the case with developments, for example, of projects that receive funding, we speak of external projects. Contracts are necessary. In the V-Modell this was extended by extensions to document templates for the necessary tasks of the tendering and the conclusion of the contract. It then creates a decentralized network of employees with distributed responsibilities. All the more important is the division into Blogs, which must then be suitably distributed from a technical point of view. Another distinction when looking at tasks is, that the project can only be distributed in one country or over several countries. How do we deal with internationalization? With knowledge about other cultures the impact of multicultural diversity can increase. In addition, we need tasks for education in other cultures. In other words, in IT support. But this IT support is harder to realize because of different tools and the problems between the different tools. Also, the bills, especially in publicly funded projects are also not easy to do. There are extra jobs like the GIZ, which do these tasks by specialists. But this means that more documentation tasks have to be completed and contracts have to be concluded.

If we consider the portfolio of projects in a company, then a multi-PM for coordination by a committee for the decision-making of selection of project proposals, financing (budget finding), appropriate resource planning (or even during the project term advantageous allocation) of resources, the prioritization of projects, supported by risk assessment with impact on the project landscape and portfolio review of all projects including the holistic coordination with the corporate strategy as well as standardized reporting and performance control necessary (as seen in Bircks, 2009). Furthermore, according to Bircks (2009), a regulation on decision-making powers and instructions also applies to management during the course of the project, the establishment of a knowledge pool and the provision of project-relevant information during and after the project. The project teams must be trained in the tools and methods and standards to be used. These framework conditions for the implementation of many projects in a company are thus possible in a planned PM with the focus on expertise, in the agile and

in the anti-fragile approach can be made some compromises. For both, the distribution of responsibilities per se is clear: everyone is jointly responsible for the success. Resources can be requested or exchanged at any time as the situation requires. The immediate danger of success must be avoided.

While the team spirit of the agile approach to the high-performance team - in which team members trust each other and sometimes work more to help others - has evolved, the anti-fragile approach is such that everyone can act on their own to find the best solution to find. Accordingly, everyone also needs a certain budget, which he may spend.

Table 1. Highlighted tasks in planed, agile and anti-fragile PM

Tasks:	PM →	planed	agile	Anti-fragile
Demand		Predetermined plan (time, costs, resources, methods, standards) from Manager/ MPM to fixed team	Blogs with timestamps from Product Owner to Scrum-Master to team, new Blogs in product Backlog	Problem to group of members, the members say how long time they need
Selection of works (operational level)		assignment from Manager to person	Free selection of an increment to work on it	Free selection of an part problem to solve it
Handling of problems occurred		Solution by manager	Solution within Team	Self-optimizing search for solution
Budget allocation		MPM/ Top manager	Product Owner	Each team member
Interchange of Instructions		Planed timestamps	Daily/weekly meeting/ Sprint	If necessary
Hindsight of finished projects		Institutionally (MPM) registration through questionnaires and forms	Every day / week or at the latest after Sprint: Discussion about mistakes	Learning from mistakes, these are openly discussed

In table 1 you will see the differences of important tasks between the planed, agile and anti-fragile PM. But how different are the manifold tasks organized?

Organization

On the basis of the analysis of task complexes described above, it can be stated that companies today carry out several projects virtually at the same time and therefore use multi PM (MPM) - also called portfolio controlling or product controlling (Krcmar 2000). This can be organized differently. It ranges from a separate department, to committees that always arrive at the same intervals, to outsourced assignments from specific companies. (Gabriel Beier, 2003, pp.136-143). And how is the project carried out from an organizational point of view? In a project, team members have to work directly on (part of) project and service team members have to document the state of a project (in plan, deviations) and to assist manager. Roles will be addressed to the team members. As seen in (V-Modell: Kap. 4, Pkt2.) roles are the description of capabilities, description of roles (name and text), tasks and powers, skills profile, casting, responsible for contributor. More details you will find in Balzert (2008, pp.5, 114, 120 ff, 255 ff, 556). Many different roles (34 in V-Modell) are distinguished in project teams' roles, project

specific roles and organizational roles (V-Modell, Chap.4/3). In agile PM the master works together with the team members (specialists) after having the blogs from product owner. For the organization there is no need for roles (and the high administration). All people work together if necessary. In anti-fragile PM everybody works on his problem in his way with the method, which he wants, and if he thinks that he needs help from a specialist, he is able to claim it. This is possible because of branding management. If you have an internal project or an external global project, it is easier to put together a team as it is within a network. In cooperation with partners from different companies, the influence of multicultural diversity will increase. The advantage is that the customer requirements in these countries are better understood through cooperation.

Table 2. Organizational elements in planed, agile and anti-fragile PM

Organizational elements:	PM → ↓	planed	agile	Anti-fragile
Room for Maneuverer		Not free	Responsible for team	Self-responsible
Collaboration		Distribution according to competence, working alone within group for cooperating enterprises	collaboration among employees routinely avoid problems	Collective collaboration
Control Support Information		Project goals (operational) MPM enterprise-goals	enterprise-goals	Corporate culture, corporate strategy
Organization unit		Fixed team	High Performance Team (never change a winning team)	Each Team-member
Learning organization		Learning if necessary for the projects	Learning every time, feedback after project, motivation,	Learning every time, also from mistakes, feedback during project, Burning
Phase concepts		Planed Phases with planed results	Operation phases – no separation in construction, control and documentation – all in one	Free handling in problem solving
Roles /committees		Multiple Roles, distinguished in project teams roles, project specific roles and organizational roles, MPM, PM	Owner (Blogs), master (operational), Team	Top management with problems, solver-group
Meeting points / steering board/		Milestones, planed timestamps, Steering board outside	Blogs with date, sprint 2-4 weeks, Team: every day	If necessary, IT supported, finished, problem solved
Administration		Very high, many documentation, project History	no documentation during development only results	For IT support only,

Organizational elements:	PM → ↓	planed	agile	Anti-fragile
Perspectives		Reliability, adherence to plans,	Fast and flexible, trust	Burning for the enterprise, By stress you become better, creative, innovative
Adoption of outdated concepts		Permanent learning	Team to High Reliability team	Back to Group, Free thinking and acting
Dealing with changes		Contractually regulated, plan change before implementation	Changes are accepted by the team at any time, (Blog change)	Changes are accepted by the team at any time, (Blog change)

In table 2, we demonstrate the essential organizational elements and their changes in different pm. From setting out fixed work schedules to communicating business goals to corporate strategy, the controlling information has evolved in connection with finding a new product or solving a problem. When dealing with changes, the need to make changes at any time, from the fragile inability to make an exact plan to the development of a product or service, has made this the immediate change self-reacting to changes. Thus, minimal damage and maximum profit for a company can be achieved in the simplest and fastest way possible.

Instruments for PM

In this chapter we discuss the different methods and the necessity of special IT Support. In planed PM the manager needs many methods to decide, to plan, to document and to control the project. For the different phases exist different instruments (see more in <http://www.infforum.de/>) Virtual Organizations are a set of organizational that rely on multiparty co-operative relationships between people across structural, temporal and geographic boundaries. Flexibility is brought about in part by reconfigurable networks of computer based communications that allow organizations to co-ordinate their activities and in part by a management philosophy based on collaboration and innovation. The required decentralized computer-assisted collaboration of time- or space-separated teams and groups is supported by groupware.

In table 3 we answer the initially question asked after possible supporting instruments for PM. Here we show, that the tendencies of only thinking about the problems as specialist of certain subjects is today not enough. Therefore, boundary conditions as enterprise strategy, possible measurements to act or to react on different conditions have to be taken into account from all team members in anti-fragile PM. In contrast to this fact, in agile PM, on operational level only the product owner has to know a great part of these conditions, the product owner all conditions, and all others a subpart of these. In planed PM there exist no call for this knowledge.

Table 3. Some Instruments, used in planed, agile and anti- fragile PM

Instruments ↓ P M →	planed	agile	Anti-fragile
Plan tool	Gantt chart, PERT chart, Microtool, project plan	Calendrer for blogs-time stamps, Excel,	Groups Work
Control	Developing Key figures, Reporting	Daily/ Sprint – Meetings	result
Needed control information	Explain the project objective	Explain the enterprise objectives	Explain the enterprise strategy, corporate culture, explain the problem
needed methods	Strategy – a knowledge for top management, BSC, phase concept, COCOMO-Model, Function point analyses, for more see INFFORUM	Quality management, Risk management, Strategy – a knowledge for product owner,	Brain storming methods, 5 Ps for strategy, Ansoff Matrix, Porter's Competitive strategies, Theory of Constraints
techniques	Fishbone technique,	Lano-Diagram, Classification and dismantle Marketing techniques	Fishbone technique, Lano-Diagram, Classification and dismantle, Scenario techniques
standards	UML, SysML IEEE1471	UML, SysML	UML, SysML
IT-Support	Tools for planning, information, coordination	Communication, Collaboration	Communication Cooperation
platform	Collaboration platform (p.e. Mikrotool)	Collaboration platform, (p.e. Mikrotool)	High dependence, therefore ensuring high availability

Conclusion: more persons have to know about the so long hidden information about the enterprise strategy, and they work today on the bundle of strategies for implementation of the wished enterprise strategy. Because of changing environment with many unknown conditions the theory of constraints is born. In this theory the security buffers for time, costs and worker are given – only one for each – but enough - for the whole project. Gone is thinking in 100% planning. With these buffers, it is possible to think about reactions rather than just drifting. Unforeseen events can be answered quickly. Goldratt (1997) uses a half-time estimate of the durations (i.e., the most frequent durations) as a simple approximation of the durations. The temporal buffers (e.g., difference between optimistic duration and pessimistic duration) are cumulated and appended to the end of the project as a shared buffer. The common buffer is not necessarily the sum of all individual buffers, but can be shortened according to statistical laws. By actively announcing the termination of a work package, it is attempted to line up consecutive processes as possible in the relay-run principle and to avoid idling. "And without the ballast of coordination with others, resolute decisions can quickly be made in a company such as in an emergency room of a hospital (see also Techt, 2017) act. The old slogan "What does not kill us, makes us stronger" is alive.

Discussion

We discuss now our findings above the aspect of cooperation. Under cooperation we understand an exchange of information over a synchronous channel between at least 2 persons or smart objects for decision making about the disposal of a resource. Thus, for example, in the case of a bottleneck, an order can be negotiated as to when and who may use the object in dispute in which chronological order. A good communication channel is therefore necessary to conduct the negotiation well. Conflicts should be avoided. Cooperation therefore focuses on the appreciation of the individual or the negotiating skills. This includes persuasiveness, creativity, good and clear language and the use of the right communication medium. If in a project each team member is responsible for one subpart, the person responsible for the entire project has to be able to coordinate well. "The lowest common denominator is always the individual employee, the individual person and how he confidently deals with his tasks as well as into the project Team is integrated ". (Quoted Bergauer, 2018).

Aarmor, Phillip G: "The Laws of Software Process" states in his book that we are re-engaged in a learning process in each project. The difficulty of this learning process is that we usually have to set up a plan for a project at the beginning. Our usual solution to compensate for "unknown unknowns" is to schedule buffers. We derive their size from the experience we have already gained in terms of requirements. Since the product to be developed in the software area is to be expandable and parts to be reusable, developers are forced to look to the future and take eventuality into account. The object-oriented approach was created specifically for reusability. But as completely new technologies or knowledge can make all the work so costly lapses, the question is when and what decision should be made in this case of software development in design of architecture. For this purpose, it must be read in (Techt, 2017) that as late as possible a decision should be taken, which then inevitably narrows the options.

On the question of whether the whole thing is financially worthwhile, studies have to be mentioned. Techt refers in his article (Techt, 2016) to a study by Dr. med. Alan Barnard, about multitasking in PM with approx. 500 participants from 20 sectors, according to which 20 percent capacity and 25 percent of sales are lost. According to Wolfram Müller (referred by Techt, 2016), the methodology of critical chain PM (CCPM) can also accelerate projects by around 20 percent or more. Combining Scrum with Critical Chain (= Reliable Scrum) this leads to Lorenz (Lorenz, 2014) to more success as the only use of agile methods. Following the fact that resources are usually not available indefinitely, projects therefore have to be successively bottlenecks. CCPM gives priority to project to which the division project progress on critical chain to use buffer is the lowest. According to (Lorenz, 2014), the use of CCPM in multi-project management can lead to an increase in adherence to deadlines of 95% and to a reduction of project durations by 25%.

The new success factors arise from the consideration "to get the best out of all situations which means that the enterprise is able to serve all customers on time and without quality compromises even in times of (significantly) increased demand". (Techt, 2017) While agile ways of working focus on adapting to new circumstances, antifragility focuses development by new circumstances. First approaches of agile features - as written above - were given in evolution model, incremental model, spiral model and prototyping. In agile PM Trust in the team becomes important here in the team to

achieve maximum performance. In the anti-fragile approach, trust is also demanded from the company to the employees in order to be able to drive innovation. In the agile approach, "the most efficient and effective way to communicate information to and within a development team is in a face-to-face conversation" (cited from agile manifesto). That's why the daily / weekly meetings - in eXtreme Programming (XP) minutes / hours - are very important. In this context, the Four V's, Volume, Variety, Variation and Visibility are also very important. as seen in (McDonald, 2008), which were dealt with in the context of the tasks. Thus, the table of most important criteria looks like this:

Table 4. Comparison between planed, agile and anti-fragile PM

Criteria ↓	PM →	planed	agile	Anti-fragile
Given Plan		CPM, Fixed project plan, fragile	Blogs, flexible, robust	CCPM (Buffer), LOG-Book, Do what the situation demands
Fast to market		Not relevant after planning	Fast to market	Innovation (earlier as others), multiple Options maintain
Responsibility		Each member himself for Adherence to the plan	Responsible for the result of the team	Self-responsible, high commitment

Critical Path Method (CPM) is referred to in (Rouse,) as a "A step-by-step PM technique. "However, since as many of the options as possible have to be retained in the development of a product or service, one must "deal more intensively with the question of the last possible time of a decision than deal with the decision itself. ... CCPM no longer presents resource scarcity as an exceptional situation, but considers it a normal case "(quoted by Gerrit Beine (2015)).

Summary

While agile methods of PM require the required skills of the team members in communication, the team members in the anti-fragile approach rely more on the cooperative style of working. New success factors are considered to be action on market. To do so much more self - responsibility from the team is demanded but also more trust into team members on the side of top management. While the agile PM can survive robust surprise, the anti-fragile PM learns from it and gets even better. For example, bottlenecks are optimally utilized. Priorities that everyone can see at any time "ensure that managers have to settle fewer conflicts and put out fires." (Techt, 2017) Employees may also exceed or fall short of schedules. This then serves as experiences that will be incorporated into the next estimates. Responsible supervisors must ensure multitasking among employees. (Lorenz, 2014). In the anti-fragile approach, the right corporate culture plays an important role.

When perturbation occurs, fragile and robust systems - supported by planned PM - are destroyed, resilient systems - supported by agile PM - recover, while anti-fragile systems benefit. In cases where market conditions do not anticipate changes in project

development time (e.g. through standardized arrangements), content can be planned and defined, and projects are characterized by a short development time or are developed for a closed market, then a planned approach such as waterfall can be successfully applied. But if customers want new materials or techniques during the project, only agile PM or anti-fragile approaches can provide the necessary additional values such as freedom of choice and ownership. If your team is not as self-dependent as it is needed for an anti-fragile approach, or if the company is not yet an agile system, then an anti-fragile approach is not possible. The challenges of PM are the differences in goals: PM is seen as mastering the complexity with collateral and standards compliance (like waterfall), or PM should serve customer satisfaction taking into account the risk minimization (agile) or the project should be profitable for that Companies, even if risks have to be taken into account in a dynamic market (anti-fragile). Action is better than to be frozen in fear.

WHEN RISK MANAGEMENT IS NOT ENOUGH: PROJECT MANAGERS' EXPERIENCES WHEN CONFRONTED WITH THE UNEXPECTED

Andreas G.M. NACHBAGAUER

University of Applied Sciences BFI Vienna
Wohlmutraße 22, 1020 Vienna, Austria
andreas.nachbagauer@fh-vie.ac.at

Abstract. *Some organizations try to manage complexity by transferring it into defined, controllable structures and processes, aiming at delivering outcomes in a predictable and reliable manner. Others trust a high degree of freedom at the shop-floor and team level allowing for quicker decisions and self-determined choice to successfully respond to unexpected events. This paper explores the questions "What are organizational conditions and what course of actions allow project managers to handle unexpected turbulences satisfactory?" Empirical findings on both organizational cultures and structures, and a set of typical routines for managing unanticipated situations using eight case vignettes are presented. Results show that successful project-oriented organizations tend to relax structures and empower teams when confronted with sudden events in the detection phase. Once the decision on actions needed to address the turbulence is made, smart organizations swiftly rebound to formalized hierarchies and clear communication structures in the recovery phase, allowing for quick and coordinated action. Thus, combining centralization with decentralization along the timeline of resilient action is one of the cornerstones to smart project organizing.*

Keywords: *The unexpected; project resilience; organizational culture and structure; case vignettes.*

Introduction

Risk is calculable, and predictions can be expressed by a statistically or mathematically determined probability (Acebes, Pajares, Galán & López-Paredes, 2014). Uncertainty, on the other hand demarks events in the future that are unknown, and/or their consequences cannot be estimated. Uncertainty, when transferred into calculable risk, seems to be manageable in standardized and formal processes (Machina, 1987; Zhang, 2011). Traditional project risk management approaches are rational and sequential, following a control-and-order logic. Thus, some organizations increase direct control, reduce trust and transparency when faced with project turbulences (Loosemore, 1998; Söderholm, 2008). Only recently this control-oriented stage-by-stage approach has been challenged (Brady, Davies & Nightingale, 2012). De Meyer, Loch and Pich (2002, p.61) require project management 'to go beyond traditional risk management, adopting roles and techniques oriented less toward planning and more toward flexibility and learning.' Following this proposition, organizations react with elasticity, such as agile project work, ad hoc teams and expert pools, fluid and adaptive structures (Geraldi, Lee-Kelley & Kutsch, 2010).

Winch (2010, Winch & Maytorena, 2012) coined the spectrum of growing uncertainty by the labels of known knowns, known unknowns and unknown knowns. Ultimately,

unknown unknowns demark the passage from uncertainty to the unexpected. For surprising situations that long for a long-term reaction, organization will have enough time to search for additional information, calculate by advanced analysis methods, and plan in-depth and in advance (Duchek & Klaußner, 2013). Here, traditional risk management will be sufficient. However, issues become more complicated in case of urgency. When risk management is not enough, new procedures must be implemented to manage the unexpected.

In this paper, I explore the question “What organizational preconditions allow project managers to handle unexpected turbulences satisfactory?” I will present empirical findings on both organizational cultures and structures that support effective management of the unexpected and outline a set of routines for managing unanticipated situations utilizing eight case vignettes based on interviews with practitioners.

Handling the unexpected in project management

The unexpected is that event, that one does not expect – that sounds trivial. Inspired by social construction theory (Maturana, 1982; Foerster, 1984) I insist that the expected and hence the unexpected are not entities in themselves, but are “produced” by and from the perspective of an observer, either an organization, an employee or a team. The unexpected can only be understood in relation to an observer. Observations are not deliberate, however; they are structured. Within organizations strategy, organizational rules, culture and so forth define what can be expected and what is unlikely. The unexpected reflects “the actuality of projects as social processes requiring ongoing construction of the appearance of certainty and clarity in the midst of complex uncertainty and ambiguity” (Atkinson, Crawford & Ward, 2006, p.696).

Perminova, Gustafsson, and Wikström (2008, p.74) claim that the exposure to uncertainties requires an open approach less oriented towards planning: “Projects are better described as journeys of exploration in given direction, rather than strict plan-following endeavors”. Managing uncertainty in projects is based on experience: being explorative, associative, sensual and in intense relation to the project environment (Heidling, 2015). Atkinson, Crawford and Ward (2006) suggested that uncertainty management asks for trust building, sense making, organizational learning, and an appropriate organizational culture.

Saunders, Gale and Sherry (2016) and Saunders (2015) analyzed project management responses to project uncertainty taken from high-reliability practices. In their empirical study on civil nuclear and aerospace projects, they found out that project manager adopted high-reliability practices for managing uncertainty in projects, inter alia with regard to an open and no-blame learning culture, decentralized decision-making processes and mindfulness. However, some of the practices were fragile, with structural factors, such as complex ownership structures or short-term incentive mechanisms, threatening high-reliability project organizing.

Johansen, Halvorsen, Haddadic and Langlo (2014) developed a nine-step framework for identifying, analyzing and managing uncertainty. According to Johansen (2015), project team members should be entitled and even stimulated to express their concern in regular uncertainty analysis workshops. It is important that project owners become actively involved in managing uncertainty in projects with a „hands on“ rather than a

„hands in“ attitude. Learning and knowledge creation are seen as essential parts of uncertainty management, which need to be followed systematically in a supportive, dynamic reflective process.

Recent developments in the organization of work such as agile and lean project management, design thinking, holacracy or the open-source movement are proposing non-traditional ways of coordination to deal with uncertainty as a central feature for projects. These approaches tend to replace foresight and avoidance by consciously allowing for insecurity in favor of a look forward (Drury, Conboy & Power, 2012). Within these structures, accountability for the work is shared and knowledge is more important than authority. As all these forms are short cyclical and inspire participative and responsive structures (Bernstein, Bunch, Canner & Lee, 2016), this allows for a more flexible approach towards managing uncertainty. A no-blame culture and high transparency ensure permanent and joint learning.

Methodology and sample description

This paper presents results from an empirical study conducted in Austria in spring 2018. P-M-A¹ members and project managers found in the university database were invited to respond to an online-based screen-and-keyboard interview.² Despite the call for theoretical sampling in qualitative research (Yin, 2014; Strauss & Corbin, 1990), responses and thus cases are based on self-selection for practical reasons. Still, we ended up with a quite diverse sample, allowing discovering commonalities and differences, and generalization by type formation. Controlling for structural variables encourages the presumption that the vignettes show exemplary value.

The first part of the semi-structured online questionnaire centers on dealing with uncertainty in a distinctive project, asking for the project managers' experiences and actions in this situation. This part roots on a framework combining two dimensions of consideration: The social dimension comprises the project manager, the project team, and other stakeholders, the time-related dimension unfolds along the occurrence of the unexpected: before, during and after the event. Ultimately, we demanded respondents to assess, whether turbulences could be properly handled by actions taken. Results of the first part of the interviews are summarized as cases vignettes.

A second part concentrates on the embedding of the projects into the organization along the dimensions provided in literature. We expected results to refer to influences on the course and outcome of the project in the dimensions of project orientation, project environment, project sensitivity and mindfulness, project design, project team and project knowledge (Borgert, 2013; Saunders, 2015).

We asked the respondents to assess the organization's overall structural characteristics in the dimensions of (oriented to Bleicher, 1970):

- formalization grade (high – low)
- distribution of decision-making power (central – decentralized)
- decision-making process (individual – collegial)
- information relations (bilateral – multilateral)

¹ Project Management Austria (P-M-A) is the Austrian Member Association of the IPMA.

² Interview guide construction and data collection were conducted by Edgar Weiss, Iris-Schirl-Böck, and the author, all UAS BFI Vienna.

To determine organizational culture, we employed the two dimensions spanning Deal and Kennedy's (1982) typology: speed of feedback vs. readiness to take risks. Moreover, we asked the respondents whether the organization they work for defines itself as project-oriented organization. A final set of questions inquired on the organization's and the project manager's demographics (Table 1).

We ended up with eight usable vignettes of incidents and companies, all of them ranked as large enterprises (more than 250 employees). All of the respondents display long term and international experience as project managers; most of them having an additional function within their company besides managing projects.

Respondents of case 1 to 4 reported that the organization/project was able to handle the unexpected turbulences successfully, while case 5 to 8 were deemed to be failing to manage the incidents properly.

Table 1. Sample description (own source)

Characteristics	Case 1	Case 2	Case 3	Case 4
Industry	IT	Consulting	ICT	IT
Project-oriented org.	Yes	Yes	Yes	Yes
Experience as PM (years)	28	12	20	20
Additional functions	Cadre	Staff	Expert	None
Gender	Male	Male	Male	Male
Age group	40-49	40-49	50-59	50-59

Characteristics	Case 5	Case 6	Case 7	Case 8
Industry	Telco	Services	IT	Electronics
Project-oriented org.	No	No	No	Yes
Experience as PM (years)	15	20	15	10
Additional functions	Manager	Staff	Cadre	Expert
Gender	Male	Male	Female	Female
Age group	50-59	50-59	40-49	50-59

Findings

Those organizations that reported to handle turbulences more satisfactory are characterized by a higher formalization grade and more bilateral information relations; the decision-making power is more centralized and the process more individually organized. This is in line with the observation in the data that efficient, organized and centralized communications after decision-making prevails – but not in line with previous research. Even more so, contrary to literature no systematic relation between positive project orientation, awareness of the project environment, project sensitivity and mindfulness, project design, project team openness or shared project knowledge on the one hand and successful handling of the unexpected could be found.

The well-known matrix of culture types by Deal and Kennedy spans a 2x2 matrix between the dimensions of the degree of risk associated with a company's key activities and the speed at which companies learn whether their actions and strategies are successful. In this study, the typology of readiness to take risks and the speed of feedback allowed to identify clear-cut categories and to place the vignettes with the matrix (figure 1).

Figure 1. Position of cases within Deal and Kennedy's cultural model
(own illustration based on Deal & Kennedy, 1982)

Process cultures

Process cultures (bureaucracies) are characterized by low risk, i.e. errors hardly occur, and if so, they do not cost much. Rules are carefully followed in the absence of effective determination and controls for success. Two of the cases resemble process cultures.

Case 1 features a worldwide rollout of a new server infrastructure for a customer after outsourcing; the project is very complex, external, very large, and international. Turbulences started with new regulations within the own company, which had to be applied immediately to the current project – and this is a challenge especially for process cultures. The project manager got aware of problems when releases for much-needed hardware orders were kept back. Both the project manager and the project team faced and analyzed the situation. It was the project manager alone that made the ultimate decision to comply with new processes and to exert political influence on the necessary decision-makers in the root organization, but with justification to and information of the team. The decision was actively supported. The interview partner named keeping calm and communicating as key success factors. According to the project manager, the turbulence could be handled to the utmost satisfaction.

Case 3 is about computer hardware. The project is complex, internal, medium large, and national. Turbulences embarked, as the customer was suddenly no longer available because of reorganization. Thus, requirements were partially implemented. Actually, the project manager was formally informed by the parent organization that the project principal is no longer available. Losing clear-cut direction on „What and how do we continue?“ leaves process cultures in distress. It was the project manager who was affected in the first place, and he, together with the customer, analyzed the problem and decided for a project re-and de-scoping together with the new project client. With this decision actively supported by the team, the turbulence could be handled in a very good way. Named key success factors were a long-term PM experience and cooler head, rational thinking and social skills.

Tough-guy, macho cultures

Individualists who enjoy risk-taking and who get quick feedback on their decisions will dwell in tough-guy, macho cultures. This is an all-or-nothing culture where successful employees are the ones who enjoy excitement and work very hard to become stars.

Case 2, a consulting company, is a prototype of this culture. In a complex, external, very large, international consulting project for a large international energy company, the task was to implement energy efficiency measures. Strategic decision by the client to close nearly 1/3 of sites and to significantly renew and automate the infrastructure of the others ignited the turbulences. The energy efficiency project was cancelled, instead an automation and therefore personnel reduction project was implemented. The project manager identified the problems through repeated discussions with the customer representatives: Suddenly, talks centered around another program spread and which immediately attracted attention. While detected and analyzed by the project manager and the team, the ultimate decision was made by the project steering committee together with the customer, but with justification to and information of the team. First, the project has been postponed until the planning results of the automation project were clear, then, a reduction of scope in the energy efficiency project was communicated. Ultimately, the project was cancelled with the consulting company paid for the previous services. The key success factors named by the respondent very much questions the efficiency of the tough-guy culture: Significantly reducing risk appetite; writing is much more important than verbal agreements; proactively asking when decisions are delayed; discussing concrete solutions, not the problem; keeping cool. In line with the cultural features, the project was coined a full success from the viewpoint of the consulting company, despite it was cancelled.

Case 4 shows a quite regular start of a project in competitive settings: Implementation scope of the complex, external, medium large and national project was agreed with the customer only in the pre-phase, but the implementation time and the budget have already been fixed before. Turbulence commenced from the contract creation phase on, as product sheets of hardware and software were defined as part of the contract, but some of the functions of the software were not suitable. The identification of the technical troubles involved both the project manager and the team plus discussions with external specialists. These experts were also involved in analyzing the problem and making suggestions, while the decisions to search for alternative solutions, rescheduling and additional resources rested with the project manager and team experts together with the steering committee. Key success factors for handling the turbulences to the satisfaction of the project manager where flexibility in action, rapid integration of the management, and stability in project management and communication.

In Case 5, turbulences could not be dealt with to the project manager's satisfaction. The aim of the very complex, external, very large and international project was the modernization of a mobile network. Minor quality of construction companies and hardly defined processes caused problems for the project manager and the team. These were analyzed by the project manager, and the decision based on proposals from the team were measures for quality and process improvements. While the decision was actively supported by the team improvements were still low. Learnings were to keep calm, follow a structured approach, and take time to reflect and plan.

Case 7 also failed to solve the turbulences in a proper manner. The medium complex, external, medium large, national IT project had turbulence with a supplier. Identified by the project manager, she analyzed the issue together with team experts and decided after involvement of others before decision.

Analytic project culture

Bet-your-company cultures, as it was originally coined, are characterized by high risk and low or slow feedback. The result are activities that record and reduce risk. Because the need to make the right decision is high, the culture is long-term focused with a collective belief in the need to plan, prepare and perform due diligence at all stages of decision-making. I will thus rather call them analytical project cultures.

Case 6 is an IT project devoted to making improvements to the mainframe to ensure ongoing and future operations. This is an external, national project of medium complexity and size. Problems stem from lacking acceptance despite clarification with the technical decision-makers before the implementation start. This led to a long delay in the implementation phase and stakeholder dissatisfaction. It was the project manager to identify and analyses the trouble and to decide on solutions based on proposals from the team. Unable to handle unexpected issues and deviations from plans, as is common with analytic project cultures, the organization was ultimately not able to deal with the turbulence properly, despite the decision being actively supported by the team.

Work hard - Play hard

The work hard, play hard features low risk and rapid feedback. Employees are risk averse; however, the feedback on how well they are performing is almost immediate. Employees in this culture have to maintain high levels of energy and stay upbeat. Stress is coming from quantity of work rather than uncertainty.

Case 8 is less an example for work hard - play hard cultures but better understood as a project in a high competitive market: Here, stakeholders systematically and intentionally under-estimate project costs and are over-optimistic about project benefits and schedule in order to get the projects approved (Sanderson, 2012). The medium complex, external, medium large, international customer project was won with a high competitive offer. Compared to the original estimates, the project management effort was greatly reduced, the effort for customer workshops was far too low. Already in the first weeks, it became clear that the project was not feasible within budget and time. On the one hand, the customers insisted on adherence to the schedule, but on the other hand, they were not able to persuade their own employees to work efficiently. The project manager soon identified these issues and analyzed it together with external experts. The project sponsor and the project steering committee decided to re-calculate, and to order overtime and weekend work. Contradictory arrangements, detailed records, receivables and counterclaims followed, crisis meetings led to tight-knit controlling. Ultimately, the project was called to a halt. Contrary to all the other projects, communication even after the decision was very inefficient and very chaotic.

Discussion

In the case reports no systematic connections between successful handling of the unexpected and features normally ascribed to resilient organizations, i.e. orientation towards the environment, sensitivity and mindfulness, higher readiness to accept diversity and equality in the team, were found. Even more so, successful organizations are overall characterized by a higher formalization grade, decision-making is centralized and individualistic, and bilateral information relations prevail. In addition, not just the complex projects were most likely to fail, as predicted by literature (Sanderson, 2012; Saunders et al., 2015). To some extent, the missing nexus can be explained by the fact that all organizations studied ranked very high on the respective dimensions of resilience orientation mentioned above. Now, is literature wrong to suggest this correlation, or is my dataset weak? However, organizations that defined themselves as project-oriented are more apt to manage sudden incidents. We did not explicitly ask for structural or strategical characteristics of project-oriented organizations (PM methodology, PMO, PM standards a.s.o.), so the study might fail to see the role of structured and formal instruments of project management. Nevertheless, based on answers to more general questions all organizations seem to have the appropriate PM-institutions and instruments at their disposal.

Looking more closely to the vignettes, data suggests a more convincing answer. Project-oriented organizations are not more successful in handling sudden events because they show typical instruments and institutions of project-oriented organizations, but because they respond smarter by making a flexible use of these characteristics. I found that smart project managers used to integrate the team in both the detection and analysis phase and in the preparation of the decision. Moreover, turning to experts obviously did not improve results. Contrary to the rather flat and empowering features in the coping phase, communication after the decision how to proceed was very efficiently organized and centralized again. Obviously, organizations managed swiftly to adapt their style of management to the needs of the situation.

This behavior is in line with recent insights in research on organizational resilience (Barton & Sutcliffe, 2017). Välikangas (2010), Hamel and Välikangas (2003) define resilience as the ability of a system to resist major changes and thus endure perturbation without systemic change, while Ortiz-de-Mandojana and Bansal (2016) stress the organization's ability to sense and correct maladaptive tendencies and cope positively with unexpected situations. Summarizing, organizational resilience is the ability of the organization to rebound from adverse and unexpected situations towards the right path to success. When being confronted with the unexpected, resilient project managers, project teams and the organization align their actions along the timeline: (1) anticipation, (2) detection, (3) recovery and (4) adoption. I will concentrate on the second and third phase.

In the cases, I find proof for the hypothesis that the unexpected – or at least the surprising momentum of the unexpected – depends on the observer. The surprising occurs mainly in those areas, which run counter to the basic assumptions of the respective organizational culture. Expectations can develop into blind spots where unexpected events can develop and become unmanageable (Weick & Sutcliffe, 2007). For example, process cultures were challenged by new and quick to implement regulations, and loss of clear-cut direction. Tough-guy cultures took the risky road by ill-

defined project charters, and analytic project cultures had troubles to handle unexpected issues and deviations from plans.

In the phase of detection, individuals, the team and the organization focus on traces of the unexpected by the application of a wide range of tools, including weak signals. Questioning known routines is crucial in this phase, and this might explain why project managers in complex projects are better prepared to handle the unexpected. Put simply, they are readier to expect the unexpected, while in simpler contexts they might stick to their well-trained routines for too long. Barton, Sutcliffe, Vogus and DeWitt (2015) talk about a-normalizing, taking proactive steps to become attentive to deviations, to understand them better and more fully, and to be less attached to history.

Coping starts with accepting the unexpected. While not every unexpected event triggers a crisis, the potentially threatening unexpected that requires a short-term response breaks up the organization's normal operations. Especially for stable organizations and strong organizational cultures, accepting a serious problem or a potential crisis is difficult. Denying and repressing the need for change are common mechanisms. The final stage of the detection phase is sense making (Weick, 1988, 1993) and the search for targeted action. In this situations openness, team learning and knowledge sharing, helps the team to discuss and negotiate its way to a plan of action matching the specific project situation.

Once decided on necessary actions, quick response and unquestioned direction is needed again: Undisputed hierarchies and rules have a relieving effect for decision makers, both subordinates and supervisors: they need to take into account those facts only that are within their formally. To avoid information overload and allow for quick action, communication must be intensified and at the same time more restricted, specific and selective (Sutcliffe, & Vogus, 2003, Barton & Sutcliffe, 2010). Clear and bilateral communication structures and a shared language accomplish that. Smooth coordination, common orientations towards a new goal and a strong sense of mission instil both a basis to act on and stabilize the emotional situation

Obviously, in these phases different capabilities and mind-sets are necessary, both of the organization and the individuals involved (Duchek, 2014). Initially, empathy and attention for small deviations are needed. Later, clear and decisive actions and interactions connected to leadership should prevail (Barton et al., 2015). The subsequent learning process should again include the entire organization.

Summary and limitations

Successful project-oriented organizations tend to relax structures and empower teams when confronted with the sudden events in the detection phase. What is seen as an unexpected event depends on the organization's perception. Specific weaknesses in perception – organization-specific „blind spots“ – constitute the main gate for surprises. In this phase, integrating diverse viewpoints beyond well-trained and immediate answers seems to be vital. Outcome of this phase is a shared situation awareness of the project's state and joint sense making. Once the decision on actions needed to address the turbulence is made, smart organizations swiftly rebound to formalized hierarchies and clear communication structures, allowing for quick and coordinated action in the recovery phase.

To sum up, properly handling the unexpected depends on the concrete action, while general success factors are too simple and single-sided. Managing the unexpected demands, the combination of centralization in a culture of clear decision-making structures and responsibilities before and after the event, but decentralization with a high degree of flexibility and open communication within the event.

With this paper, I intend to contribute to the practice of project management, especially when handling unexpected events. However, more and broader empirical research is needed to analyze projects' processes of organizing and decision-making in the context of uncertainty. Self-selection of respondents might distort and bias results. Future research based on in-depth case studies and theory-driven samples may stress the effects of a larger project's complex organizational structure, with many different layers and autonomous entities involved on managing the unexpected. Another empirical research line may gather quantitative data to clarify antecedences, course and consequences of the process of anticipation, detection, recovery and adoption for projects and project-oriented organization. We did not explicitly ask for structural or strategical characteristics of project-oriented organizations, for instance methodology, existence and role of PMO, process and project management standards, though they might play a vital role when addressing the unexpected. Given the limits of this article and the concentration on another argumentative strand, we believe that these issues should be tackled in separate papers. Ultimately, more theoretical consideration is needed to combine research on project management and research on resilience in organizations.

IMPLEMENTING PROJECT PORTFOLIO MANAGEMENT IN A COMMERCIAL BANK

István CSENDES

Corvinus University of Budapest
Fővám tér 8. 1093 Budapest, Hungary
istvan.csendes@uni-corvinus.hu

Abstract. *This paper aims to contribute to the general knowledge of Project Portfolio Management (PPM) by presenting a case study on the implementation of Project Portfolio Management in a Hungarian Commercial Bank. In the first part of the study, I briefly discuss the concept of PPM; then based on international surveys, I write about experiences gained in its operation. In the second part of the study, I describe the most important findings of an exploratory case-study based research regarding the practical implementation of the method in a Hungarian Bank. This case-study also builds on the results of previous surveys. According to these two main concepts are highlighted: the organizational implementation of the PPM and the PPM development in practice. The most important conclusions are the following: In the examined case it is the introduction of a reporting-operating Project Portfolio Management Office (PPMO). The general conclusion is every PPMO has to be tailored to the needs of the organization. In this process, the role of top management should be considered which has two dimensions. 1) The ideation process is top-down or bottom-up 2) the top management is part of the operative implementation of the ideas or it has only a supervisor role.*

Keywords: *project portfolio management; strategic management; project management; commercial bank; case study.*

Introduction

Project Portfolio Management is crucial in the situation where the organization has to face problems arising from the simultaneous implementation of multiple projects. While thinking of projects is becoming more and more common in many areas, it is also necessary to ask whether the many projects together are an optimal system in the given organization. Does this system adequately support competitiveness, optimum resource utilization, and organization goals? Top managers have already found this dilemma. Thus, Project Portfolio Management is increasingly being used to improve the operational efficiency of business and non-business organizations.

Although this dilemma and its reflecting concept (PPM) are well known and literature on advantages, problems and applications are abundant, in a country (Hungary) wide level, there is lack of deep scientific understanding of these issues. There are very few references for project portfolio management in the listed Hungarian scientific publications (MTMT-www.mtmt.hu). An MTMT search for the English words “project portfolio management” in the title of a study produced only 2 authors and only 4 hits: Ligetvári (2013, 2014) and Csendes (2017a, 2018).

As in Hungary, neither the topic nation-state research nor the industry-wide research has quasi no precedent, so the indirect purpose of this paper is to report on the

beginning of such a professional work. To do so, in the first part of the study, I shortly interpret the concept of PPM; then based on international surveys, I wrote about experiences gained in its operation. Then, in the second part of the study, I describe the most important findings of a case study concerning the implementation of project portfolio management in a Hungarian commercial bank.

The concept of Project Portfolio Management

PPM is naturally linked to project management (PM), but it would be a mistake to interpret it only as a further development and expansion of the latter, since its basic concept covers not only the work planning, organization, and monitoring tasks of the PM, but it is also applicable for the management at the highest level. In fact, we are talking about the task of implementing the strategy. (Rajegopal et al., 2007) Strategic management's basic idea can be easily paired with PPM, because simplistically: organization on the one hand „diagnoses” and, on the other hand, it acts. This duality appears in a variety of ways in classical strategic management literature - e.g. the concepts of strategy formation vs. strategy realization in Mintzberg et al., (1998). It is easy to understand that projects represent the change in the life of an organization, in fact ultimately embody "strategic" action. In addition, in the normative sense, future changes (sometimes in the form of a large number of projects) must be deliberately and effectively managed, in order to achieve organizational goal(s). Project portfolio management offers this option to top management.

PPM focuses on the "high level" value creation issue of strategic management (strategy / advantage / efficiency issues). According to this view, PPM is a tool of operationalizing objectives and goals that is why the functioning of the organization largely depends on it. In addition, if this is the tool of implementing the strategy, it is also an embodiment of elementary interests. It is not only the guarantee of future-oriented enterprise efficiency but also the weapon of achieving benefits (and even financially measurable rewards). It thus plays a central role in the realization of strategic and financial objectives. An investment in projects can naturally be interpreted as a purely financial investment (Zdanyte & Neverauskas, 2011) in many cases. Where the profit-goals are obvious, the measurement of benefits and yields are fundamental. The maximization of rewards is expected in most cases. However, achieving these goals is not a trivial task; it rather poses a serious management challenge. It is no wonder that in the case of corporate PPM solutions considerable attention is paid to the prior portfolio evaluation models or even to the coexistence of different aspects: e.g. strategic, financial, risk (Fekete, 2017), legal, etc. This provides a strong planning, monitoring and financial characteristics of the analyzed strategic-organizational issue.

In this mission, the organization faces many challenges. These challenges derive fundamentally from the nature of the project portfolio, as the portfolio is a collection of unique but competing projects (even programs), which fight for scarce resources. Management requirements of a project portfolio thus are different from the management requirements of individual giant projects (and programs). Here, the primary challenge is that the components of the portfolio (projects) fight for their existence and for the limited resources of the company. (Archer & Ghasemzadeh, 1999; Dye & Pennypacker, 1999; Chao & Kavadias, 2008) Operating in a dynamic environment is another critical challenge for organizations (Petit & Hobbs, 2010), in which the number, composition, and interdependence of the projects are constantly changing.

Thus PPM is not simply a tool for allocating resources; it is more a method of accepting projects in the portfolio, reviewing the progress of individual projects and constantly prioritizing all projects in the portfolio. All these activities are done in the sake of balance, synergies, and success, while the project portfolio appears to be the primary field of the company's strategy (Morris & Jamieson, 2005). PPM can thus be understood as a business process the main task of which is the management of complex processes interacting with each other, helping decision-makers (to evaluate, select, rank, etc.) who, together with other members of the organization, are interested in realizing benefits and getting or giving feedback. (Wideman, 2007)

The central role of PPM in the organizational context is well understood too. For instance, in the so-called top-down approach, it is easy to interpret PPM's important role as a competency to identify and manage the most beneficial projects. Figure 1 shows its central role, especially concerning the top-down approach.

Figure 1. Organizational context of portfolio management (Source: Project Management Institute, *The Standard for Portfolio Management*, 2006, p.7)

These processes are controlled by the Project Portfolio Management Office (PPMO). These offices differ greatly from each other in their tasks and responsibilities. The task of Project Portfolio Management Office (PPMO) is not only to deliver certain projects and programs (as PMO does) but also to optimize investments to achieve the strategic goals of the organization. Moreover, it has a closer relationship with the CEOs and project/program managers. The added values of these offices -compared to the PMOs- are represented by the positive effects of cross-functional synergy. As a result of this, its scope can be much wider and can appear on the whole company level. Based on the contribution to organizational success, we can distinguish several types: there are reporting, strategic, operational, and business process changing PPMOs; they all complement each other to meet the widest range of needs. While the reporting PPMO ensures that the right information is used, decision-makers will be provided with these, the operating PPMO helps to properly implement programs and projects. Strategic PPMO supports the organization in choosing the right programs and projects. The fourth type of PPMO helps in implementing organizational changes. (Rouwendaal et al., 2014) They all have coordinating, controlling, and supporting role but to different extents,

which help to increase resource allocation efficiency, the improvement of transparency, increased the credibility of information, and wider knowledge transfer and communication. (Unger et al., 2012) Beside PPMOs other organizational players have to be mentioned: as internal involved groups have the biggest impacts on the success of PPM - the functional leaders and the project managers. (Beringer et al., 2013) Furthermore, a prominent actor appears both in the practice and in the literature: the project portfolio manager. (Jonas, 2010)

Empirical researches

Today we can already easily find out about PPM experience. For this purpose, we have scientific publications as well as surveys of professional organizations/consultancy firms. These publications deal with many aspects of the portfolio management. For example, Meskendahl discusses the success of the project portfolio in several articles (Meskendahl, 2010; Meskendahl et al., 2011). Just as Müller et al. (2008) who states -on the basis of comprehensive statistical analysis- that successful organizations have organizational level experience in selecting and prioritizing projects aligning with its strategy.

Martinsuo (2013) in her writing analyses the results of new empirical researches on project portfolio management. According to the experience, she has already drawn attention to the limitations of the interpretation of PPM as a rational decision-making process. She highlights that the PPM process in practice, compared to the classical approach, is not a rational decision-making process supporting the company's strategic objectives, but rather a series of interactions between people and organizations. These interactions are highly personal and may affect the structure of the organizations concerned.

In addition to these scientific studies, specific data can be found in the surveys of major consulting firms and professional organizations (e.g. PMI, PriceWaterhouseCoopers-PWC, Gartner, UMT). With regard to the industry's prevalence of the method, from the PWC's 2012 survey, we know that among the organizations using PPM the highest use rates were detected in retail, insurance, automotive, banking and capital market, telecommunication, manufacturing, moreover energy- and defense-industry companies.

PPM solutions were introduced firstly in Hungary, like in abroad, for multinational corporations and large public utilities. Based on the market information, without the completeness, here are some well-known Hungarian examples from early introductions. From the automotive industry: Audi, Mercedes, evopro. From the telecommunications sector: Telekom, Telenor, Vodafone. From state-service-utilities-energetics: MVM, MNB, NAV, EON, MP, Lufthansa, MOL. From the insurers: NN, Generali. From the high tech and software industry: Ericsson, NavNGo. From the primary experience of early Hungarian PPM users, I will write about a corporation from the banking sector. One of the reasons is that, similarly to foreign experience (see in the PwC Survey), we can observe PPM in this sector as a priority area in Hungary. This is a result of the "more advanced" PPM culture in the Hungarian banking sector, which is already available on expert and managerial level; furthermore, some information and experiences are accessible too.

Before discussing the Hungarian case, we can conclude that regarding the international and national situation; the 2008 crisis has hit the banking sector very seriously. In

Hungary, banks also had additional problems that due to state regulation, the sector's players had to bear additional burdens (e.g. accountability and abolition of foreign currency crediting). This is connected to Bruck (2009)'s international experience, that PM culture is still healthy in the sector after the outbreak of the 2008 crisis and despite the problems. At this time, according to project, program and portfolio managers, the main changes and challenges include the development and continuous growth of information technology (IT), the strengthening of globalization and the strengthening competition in the financial sector. IT projects are growing and IT needs of projects are growing too. This general belief -based on also market information- has been continuously proven since the crisis.

Foreign banks' practice of introducing and developing the project, program and portfolio management methodology is best known from expert reports. Publications featured case studies deal with the subject with various focus areas and depths. For example, Nieto (2010)'s publication analyses the example of Fortis bank melting into BNP Paribas, or the work of Hoffmann & Rentrop (2012) also can be mentioned, which describes the development of a bank's project prioritization methodology. Of course, other unique case descriptions could be mentioned, but unfortunately, they are not a real benchmark for Hungarian banks. Due to its special situation, the use of one of the notable Hungarian-related (Central Bank of Hungary) case study (Pap, 2010) is limited for this purpose too - as the operation of a central bank differs significantly from that of a commercial bank.

We can find relevant information for a case study about a Hungarian bank in previous years' researches if we examine it from two main aspects: project organization and bank portfolio. Those empirical studies do not mention PPMO from the organizational perspective; they present only the role of PMOs. On the Hungarian sample outside of the banking industry, Szabó (2018) was studying the maturity of PMOs. There is a similar study (Pansini et al., 2014) on the Italian bank sector. The result of that study is that there is a general need for PMOs in the banking sector.

Hadjinicolaou & Dumrak (2017) was doing a research on well-known topics (PPM and Project success) by other authors (see above: Meskendahl, Müller) in several sectors (bank sector included). This study found a connection between PPM and having project management offices (PMO) to support both project and portfolio implementation. The research results revealed that the benefits of PPM application were not seen outstandingly, the research further examined the barriers to implementing an effective project portfolio management process in Australian organizations.

Yang et al. (2015) are presenting a unique case study in a case of a large Australian bank. They were studying the PPM capabilities of IS projects. They have identifies dynamic capabilities which are the following: 1) IT Resource Integration; 2) IT Resource Configuration; 3) Resource Acquisition and Elimination; 4) Constant Change Culture; 5) Business Objectives Driving Projects; 6) The Multiple and Dynamic Prioritization Criteria; 7) Demand Management; 8) The Customized Tools; 9) Intensity of Organizational Learning; 10) Training and Career Paths; 11) Dynamic Balancing of Risk and Reward; 12) Cancelling and Reconfiguring In-Flight Projects; 13) Sensing the Environment.

The research of Csendes (2018) is the most important in this topic, where I studied the introduction of 6 PPM system in the banking sector. Based on this, support of top management is essential for the introduction of PPM. The appearance of portfolio managers was preceded by the operation of the Project Management Office (PMO). The introduction of this method became necessary because of the increase in the number of IT projects. There was a clear consensus among banks regarding the response to the market challenges facing the domestic banking sector and the nature of the projects launched to exploit the opportunities. Projects, programs and other works can be linked to digitization and legal compliance. Each of the banks analyzed has already had a formalized project management methodology. However, regarding the application of the PPM methodology, it is very diverse in terms of both the PPM structure and the location in the organizational structure. In addition, it has experienced that it is a problematic area of application of the method: the project dependency management, the depth of resource planning, or the acceptance of PPM structure by (non-project) business areas.

Methodology

The case study in the followings shows the introduction of a PPM system in the case of a Hungarian bank. The timeframe of the case study is from the following years of the crisis until today. For this study, a qualitative method was chosen. Qualitative research is defined as an in-depth multifaceted investigation (Orum et al., 1991), providing knowledge from the participant's point of view to gain understanding and meaning of a specific and emerging phenomenon (Merriam, 1998), which also offers a variety of evidence (Miles & Huberman, 1994). I obtained primary data for this research through a series of semi-structured interviews with a project portfolio manager of a bank. These interviews had two topics: The first topic was the organizational solutions of PPM, while the second was the details of the development of practices in management. The project portfolio manager was selected from a previous research (Csendes, 2018). The person was chosen because he was an actor in a very interesting bank case. This case's deeper details are topics for the chapter below.

Case study

In the beginnings (2010-2013) there was only an IT Project office in the bank, under the supervision of Chief Informatics Officer (CIO). The role of the office was to secure the project delivery. In 2012 they created the first portfolio management organizational department – under the supervision of the Strategic Director – which was focusing on classical portfolio management. The two departments merged in 2013 under the Chief Operation Officer (COO) and it was fulfilling the role of both. It was supervised by the Strategic Director; however, the department was called project and portfolio management office. Finally, in 2016 with similar roles and name it became a part of COO's directorate.

During this developmental period (2012-2015) the top management's need and the practices of PPMOs were different. The top management's needs were clear. Defining the projects and operatively seen the deliverables. The most important was the successful deliverable of projects. Besides that, it was an important expectation towards the PPMO to present the risks of the deliverables and the holding's external project needs. In addition, it was highly important to increase the capacity of the department.

Meanwhile, the practice of the portfolio management was like, in every quarter they suggested “rebalancing” decisions, where most of the times the recommendation was to terminate whole projects. Project managers were hardly supported, some kind of “conflict-culture” was created within the organization. That time the focus was on the introduction of a portfolio management supporting tool. The portfolio level resource planning was high (without the IT department); however, there was a lack of “demand management” too. The relationship was damaged between IT and PPMO, the trust was missing from the relationship.

That was the root cause for the PPMO could not meet the expectations of the top management. Besides that, there were serious issues with frustration and fluctuation among portfolio and project managers.

In this environment in 2016, it became a top priority to make a project portfolio management practice which can help to meet the expectations of the top management. Because of this, the professionals at the bank introduced provisions in six fields:

Portfolio planning – the introduction of demand management: Introduction to the project initiation phase. The project office gets to know of the project idea from the beginning and giving proper methodological help for a successful preparation.

Introduction of the portfolio planning calendar: Regular, quarterly executed project portfolio prioritization and rebalancing has been included on the agenda of the decision-making board, enabling the continually changing project portfolio priorities to be continuously matched to business strategy directions.

Portfolio planning – execution of the yearly portfolio plan based on the business and IT strategy: In Q4 based on the updated business and IT strategy the bank’s next 3-year project portfolio was developed in a top-down way. Project dependencies and resource requirements were decided on a high level, and a high-level schedule for the project portfolio was implemented.

Introduction quarterly rolling IT release planning: Detailed project planning made possible to plan (the most important bottlenecks of projects) IT deliverables by using two-month release windows planning, also considering technical dependencies. All of this had happened with the involvement of relevant IT experts and suppliers. This led to proactive manageability on portfolio-level operation risks.

Improved project and portfolio control and reporting: An easy-to-understand and informative project portfolio report which contains the most important results, the portfolio-level risks, and their management approvals. The regular monthly report made it possible for the management to get an aggregated report with the most important details of the projects instead of ~100 pages reports of the single projects.

Implementation of provisions to increase the delivery capabilities of the organization: The project portfolio was divided into sub-portfolios considering both dependencies and project networks. All of the sub-portfolios were supervised by a sub-portfolio manager (called “program leader”). The sub-portfolio manager became responsible for the projects to be done on time on the expected quality, the preparation of the connected projects, and the mentoring and supervising of project managers within the sub-

portfolio. With this governance model, it was possible to implement the project portfolio management tasks, at the right place and make a delivery oriented organization.

Conclusions and limitations

When creating a portfolio management office, it is a fundamental dilemma: what kind of activity is necessary to create a given organizational unit. According to the literature, the goal of portfolio management is to create a portfolio where the strategic needs are prevailing over individual projects. The created portfolio should have the highest business value within the given financial and cost barriers.

In practice, the implementation of the project portfolio is defined by the top management's needs. There are two perspectives which can be identified: 1) the top-management is led by the "helicopter-perspective" the project ideas are generated bottom-up and there is a need for selection. Or the opposite 2) the top-management is conscious in the strategy creation and they make top-down project ideation, where they are part of the implementation.

In this case study, the second version of PPM environment was identified. The published implementation was an answer to these needs. So we can categorize the examined organization unit of the bank as a reporting-operating PPMO (Rouwendaal et al., 2014).

The experiences of creating best practices in management are in line with the results of Yank et al., (2015). It should be highlighted in the Hungarian case, the portfolio management was studied at the whole banking operations (which is dominated by IS projects), while the Australian case study was limited to IS project portfolio. The 13 capabilities identified by Yank are in line with the above case study - only with the 4) Constant Change Culture, 9) Intensity of Organizational Learning, 10) Training and Career Paths were not supported, due to lack of information in the Hungarian case.

From the case study that can be concluded, every PPMO has to be in line with the organization's needs. In the case of the studied bank, it meant that the PPMO has to be in line with the real needs of the top management. This means in this case, it had to support the delivery of projects and controlling of project operations. In this context the goal of portfolio management was to support the top management's decision with 1) high-quality planning 2) generating inputs (resource planning, release, capabilities etc.), which makes it possible to create realistic portfolio schedules. On the other hand, there was a need for a transparent reporting system.

Information provided in the above case study is not representing the experiences of other Hungarian commercial banks. On one hand, there is not enough information which makes it accountable in the case of other banks. In the other hand based on my previous researches (Csendes, 2017b, 2018) it can be concluded, that big Hungarian banks are started to introduce the PPM in different ways, development levels, and organizational solutions. Thus, general scientific consequences for the whole sector cannot be concluded based on this case study. However, the questions mentioned in it (organizational solutions, management practices, and general conclusions) are relevant in the case of any other domestic bank. Most of all, this case study can be interpreted as an interesting benchmark case.

Finally, based on theoretical and practical considerations of the paper, a number of further research topics can be identified. Among these, I would name one: complete conceptual clarification of PMOs and PPMOs. In this context, further research works need to categorize, and explore the denominations and activities of these organizational units.

Abstract. *The economic theory on development and growth has continuously evolved, keeping the pace with the structural changes in economy. In time, it has thickened, new facets and angles having been added. Every school of thought produced their arguments and brought to the front the development factors deemed relevant at the time. The development of a nation cannot be achieved outside these schools of thought and lacking an approach that allows development factors to be identified that are relevant for the context and adapted to the respective nation specificity. However, Romania seems to follow sinuous paths in stimulating economy, sometimes very different and corresponding to various economics schools of thought and with no apparent correlation. Based on structured literature review and on analysis of different economic indicators that allow comparisons over time between European countries, this paper focuses on the identification of the real causes of Romania's economic development stagnation. It also emphasizes models that could be translated into the national practice, as well as failures of previous attempts in adopting specific models of development. The authors finally present a set of recommendations for national leaders on how to transform economic data-based decisions in a source of national competitive advantages, as a first step towards a real strategic management at national scale to achieve the goal of economic development.*

Keywords: *economic development; strategic management; leadership; economic vision.*

Introduction

Economic growth can be understood in different ways and is commonly defined as "sustained increase of a country's population and of the domestic product per capita" (Kusnetz, 1963, p.3), an exclusively quantitative concept. Therefore, economic growth is not synonym with economic development, which implies more dimensions, from wellbeing to social advances and a better quality of life. Apparently, in a paradoxical way, Romania is a country that scores economic growth, but remains rather vulnerable about development itself. The country was in 2017 the "tiger of Europe", scoring a 5.7% GDP raise, double that of the EU average (European Commission, 2017), without this

explicitly reflecting in welfare - almost 1/3 of the population states that its quality of life is worse than a year before (Starea Națiunii Barometer, 2018).

How could we explain such a paradox? Is it a stereotypical understanding of economic theories? Is it a matter of lack of vision and coherent strategy? What could decision makers do in the future to transform economic growth in economic development? We will approach all these aspects further.

Economic development: more than GDP

There is no politician in any government who would not publicly boast about raising figures that indicate economic growth in a certain time span. However, economic growth does not mean welfare or development. In time, a fully-fledged macroeconomic analysis apparatus has developed, various indicator alternatives being proposed: GDP, GNP (Gross National Product), national income. At present, GDP is, by far, the most frequently used of them in all official studies and reports that deal with the issue of economic growth and development. However, we cannot but note that, like any measuring instrument, the GDP is not exempt from issues that make its relevance when used in the topic of development questionable.

For instance, the GDP does not record intermediate goods, but only the final ones, which means that an intermediate good produced today will only be recorded in the GDP of the next one or two years, even if resources were used for its production in the present time. Also, the GDP does not record the total debt (public and private) accrued by a nation, meaning that its dynamics may originate to a high extent from an increase in the public debt that finally represents either higher taxes in the future or higher inflation by expansion, in the future, of the money supply (both diminishing future growth). Significant economic growth can be „borrowed” from the future via monetary mechanisms. The GDP does not record the underground economy („black market” exchanges), the informal economy (whatever is not formally recorded in accounting or statistics, barter trading or compensations) or financial asset investments (bank deposits, investments in bonds and shares, equity investments in funds, etc.). In such case, a strongly financialized economy can have significant welfare that is not reflected in the GDP.

Finally, the GDP does not consider the market value of the fixed assets (land, buildings, equipment, machinery, etc.) that contribute, directly or indirectly to the final goods production process (Georgescu, 2016; Bulin & Baltatescu, 2015; Fasolo et al., 2013) and systematically fails its social dimension and its relevance to the „social state”. The clearest proof of these limitations of the GDP consists in the subsequently proposed indicators, more relevant to the issue of economic growth in relation to the social state, i.e. the Human Development Index, the Gross National Happiness Index or the Social Progress Index (Mankiw, 2015).

From theory to reality

Over the time, most schools of economic thinking dealt with the issue of economic growth and development and each of the theories stated by them were put to work in strategies and policies which had inherent limitations coming out of the very stated concepts (see Figure 1), especially when decision makers do not understand and

operationalize them in a balanced strategic mix. We will present further some facts in the case of Romania correlated to literature review.

School of economic thought	Factors of economic development
Mercantilism	Money, exports, protectionism.
Physiocrats	Agriculture, population's dynamic. Limited role of the state.
Classic (liberal)	Labour productivity, capital, external trade and comparative advantages, market mechanisms.
Schumpeterian	Entrepreneurship, innovation, new products, new markets.
Keynesian	The aggregate demand influenced by monetary and fiscal stimuli, investments in production capacities, growing of the labour and capital productivity
Neoclassical	Interconnectivity of original productivity factors, markets' quality, intensity of competition, better labour force, better organization of production, scale economies.

Figure 1. Synthesis of main ideas on economic development
(Source: authors' analysis based on literature review)

Most of those who support ideas of development based on trade exchanges and state protectionism get, in fact, their inspiration in the mercantilist school of thought, who see welfare accumulation as the engine of economic growth of any nation, thus depending significantly on trade activity and on the support provided by the state. If we look to the case of Romania, we can see that the country has a real potential for exports, as their development in time proves it, but every increase of exports is very dependent on imports (Figure 2).

Figure 2. Romania's GDP dependence on exports and imports
(Source: Eurostat, 2018)

Countries having fertile and irrigable land can consider agriculture as a solution for development – an idea inspired from the older physiocrat school of thought, stating that a nation's economic growth and development mostly depend on agriculture. The main limitation of this outlook is the neglect of the other sectors of economy, like the industry and the services. Nevertheless, there are countries that could focus on agriculture, especially when having the resources. It is not, anymore, the case of Romania, once an agricultural country, where the importance of the sector in economy reduced in less than 30 years from more than 40% to less than 5%, without gaining in terms of other sectors that could produce multiplying added value, such as industry (Figure 3). We can observe an important reduction of the importance of vital economic sectors such as

agriculture or industry (without constructions) and an expansion of the trade sector, while stagnating education and health services and decreasing the gross added value in the GDP from 115,21% in 1990 to 87,7% in 2013 (Eurostat, 2018).

Sector	Year							
	% GDP							
	1980	1985	1990	1995	2000	2005	2010	2015
Agriculture	12.6%	14.1%	21.2%	18.5%	10.9%	8.9%	6.5%	4.3%
Industry	49.9%	46.0%	43.7%	29.9%	24.9%	25.0%	28.0%	23.3%
Constructions	7.3%	6.7%	5.4%	6.5%	5.1%	6.7%	9.4%	7.2%
Trade	6.7%	5.9%	6.2%	14.3%	18.4%	18.5%	13.7%	15.8%

Figure 3. The structural changes of the Romanian economy
(Source: Eurostat, 2018)

Economic development often is correlated with the need for increased productivity, an idea originating in the classical liberal school of thought. For the classics, a nation's welfare essentially depends on improving the result produced when using the original input (land, labor and capital) using higher productivity labor and increasing the capital involved in the economic processes (Smith, 1776). Romania's hourly employee productivity was in 2015 one of the lowest in the EU: index 59 vs 100 for EU28 (Eurostat, 2018).

Another school of thought with possible solutions to economic development is the Schumpeterian one. Schumpeter (1911) associated innovation capacity and technological changes within a nation with entrepreneurship and the spirit behind it. An entire school of economic thinking started from this approach, generated by an empirically proved reality: the SMEs are the largest job generator at a global level (70% of the total employed population globally), considered to be the intermediary link between growth and inclusion (Qiang & Andersen, 2016). The SMEs stimulate innovation (Almeida & Kogut, 1997), yet they have much lower resilience to sizable economic turbulences (Kerekes & Coste, 2014; Visinescu & Micuda, 2011), as it has been the case in Romania during the last decade. In Romania, the average net termination rate of the industrial companies was of -2.2% in the 2009 – 2015 period (about 1500 companies disappeared on average every year over what was newly created in the industrial sector). By comparison, in Poland the similar rate was 0.82% - about 2000 new companies annually created, while in Bulgaria the rate was 1.51% - about 500 new companies added annually to the industry (Eurostat, 2018)

Public spending, as the Keynesian (also the neo- and post) school of thought postulates, can stimulate economic growth. The Keynesian school of thought highlights two factors that can influence economic growth and development: the monetary factor (interest rate influenced by the monetary policy) and the fiscal factor (public investments). The main problem in the Keynesian approach relates to the possible inflation impact of the expansionary monetary policy and to the fact that lower consumption does not necessarily mean higher unemployment or lower investments, but it can produce ample modification in the production structure. Another critique of the Keynesian theories points to the fact that public investments are not always productive or valuable investments, being sometimes highly exposed to error. Such an example is the structure of public expenditure in Romania in 1995, compared to that of 2015 (Eurostat, 2017):

in 2015, the Romanian state spent less money on infrastructure or economic activities compared to 1995, but allocated more money to expenses of questionable knock on effect (recreational, culture and religion).

Finally, there is no economic development without economic growth, which needs capital to be sustained, and the capital can be obtained by saving. This is the outlook of the neoclassic school of thought that deems savings rate vital for the capital stock, and population dynamics important for economic growth, along with better-trained workforce, improved human resource skills and abilities, better-organized production, and scale economies achieved in the production chain/process (Solow, 1956). Romanian households' savings reached an historical maximum in 2017, of 15.98% in Q2 (INS, 2017). Nevertheless, more capital is needed to fuel the economic development. For instance, gross fixed capital formation in Romanian GDP is still low - 23.6% in 2013 vs. 19.79% in 1990 (Eurostat, 2018), making capital investments more than necessary.

Answering the limitations in the trends of thought mentioned above, the supporters of the endogenous theory of growth consider that there are state interventions that can favor long-term economic growth, with a direct impact on the rate of saving. In this outlook, additional factors associated to a nation's increased welfare are the quality and performance of the human capital, the intellectual property rights legal framework, the subsidizing of research – development activities by the state, as well as the state efforts to attract new technologies (Lucas, 1988). Another trend of thought explicitly stresses the direct role innovation, research and development and education activities have in development, and the way in which such lead to producing highly innovative goods and services that are subsequently sold in the global markets. Still, studies (Perilla, 2015; Capello & Lenzi, 2012) show that although there is a direct relationship between these aspects and economic growth, similar policies yield different results from country to country, as a function of the specific characteristics of every one of them.

Managerial implications: what should decision leaders do?

The economic theory on development and growth has continuously evolved, keeping the pace with the structural changes in economy. In time, it has thickened, new facets and angles having been added. Every school of thought produced their arguments and brought to the front the development factors deemed relevant at the time. The development of a nation cannot be achieved outside these schools of thought and lacking an approach that allows development factors to be identified that are relevant for the context and adapted to the respective nation specificity.

Decision makers of a country need two things to manage the economic development in a robust and resilient way: to understand the economic concepts that lie behind it and to correlate them more with data and less with stereotypes. There is no miracle solution for a country development, but there are ways to start and enhance it, as other examples have already proved it. Economy is after all making decisions that are constantly influenced by other decisions. Markets seek, principally, balance, but when it is not or cannot be achieved, the government intervention can improve the welfare of society (Krugman & Wells, 2014) – therefore, it is necessary to understand the factors leading to the lack of market equilibrium and implicitly to analyze possible state policies meeting such situations.

Unfortunately, Romania is a country with a very visible lack of strategic vision to guide its development. One of the aspects that prove this situation is the evolution of the economic growth itself during the last 30 years (Figure 4).

Figure 4. Romania's GDP evolution
(Source: Eurostat, 2018)

Not only that Romania's economic growth is very volatile, but it is also dependent on consumption, fueling other European economies in times of expansion and not necessary the internal production facilities. Moreover, the gaps between regions and between the rural and urban areas tend to grow, despite the cohesion policies that have been put into practice.

Among the concrete solutions that decision makers could consider accelerating the country's economic development, some seem more reasonable than others. Romania is a country where GDP has been constantly influenced by exports, both from agriculture and from industry. Nevertheless, it is the only country in the region, which experienced a profound deindustrialization situation in the 90s, as well as a very important reduction of its agricultural sector. Moreover, the structure of the industry changed from heavy industry in the 80s, to lohn textile industry in the 90s and to a more sophisticated lohn of assembling in the car industry at present. To enhance exports as a source of economic growth and afterwards of economic development, a country needs to find and enhance its own competitive advantages, from education, to research and innovation or natural resources exploitation. Strategic management postulates vision, strategy and coherence in planning and implementing operations as a mandatory condition for all development. It is not different in the case of a country and the same principle is to be applied also in the case of a potential exports-driven growth strategy. Less dependence on imports and more orientation towards local production could be robustly achieved not through protectionism, but through long-term policies that favor capital investments, as well as productivity, competitiveness, local entrepreneurship and new markets, others than the EU one.

One of the current weaknesses of Romanian economy remains the added value, in constant regression during the last three decennials. As a matter of fact, a successful exports-driven growth strategy can rely only on a high added value production, even if the beginning of the market penetration is oriented on cheap products, as it was the case of Japan in the 70s or of China in the early 2000s. From exporting cereals, for instance, Romania should consider exporting more local high value aliments. Such an approach is

possible if it is strategically assumed by the country's decision leaders and implemented coherently and constantly through well-oriented and efficient policies and regulations. To develop more complex production capacities, Romania desperately needs investments in infrastructure, in education and in research, all correlated to keep in the country as many as possible production stages.

Decision making should be data based. Too many times, perceptions seem to guide politicians when proposing so called development strategies, as we can see when there are debates about how competitive the IT&C sector is in Romania, for instance. The Romanian IT&C companies' turnover accounted only for 61.29% of the turnover of similar Hungarian firms in 2015 and only for 33.27% of that of the Polish companies with the same profile. Moreover, its value was roughly the same in 2008-2015, with only 11.5% increase in 2015 compared to 2008 and although it has a larger population, Romania had twice as many enterprises operating in high technology sectors than Hungary in 2014 (Eurostat, 2018).

Last but not least, decision making should carefully consider theories and not stereotypical understandings. For instance, growth through public debt is not per se malign for an economy, and it could look even benign in comparison with the public debt of other countries. Nevertheless, considering GDP boosting by more public debt should be carefully considered, especially if the borrowed money is not directed towards economic added value activities with a multiplying effect. Romania's public debt per capita was at a level of 3189 euro in 2016, a continuous ascending evolution from just 65 euro in 1995 (Eurostat, 2018). An increase of nearly 50 times of the public debt per capita in 21 years should maybe fuel more development than just GDP through infrastructure or education investments. Unfortunately, the state of the Romanian infrastructure is assessed by the European Commission, based on the World Economic Forum Global Competitiveness Report, with a score of 2.6 for the railway and 2.7 for the road for 2016-2017 - the last place in the EU, where 1 means very undeveloped and 7 extensive and efficient (European Commission, 2018).

Conclusions

The discussions about economic development can only be framed within the already developed and tested arguments that were brought forth by the economic school of thoughts. In this vein, the development of a nation can occur when the decision-making powers are aware of the crucial development factors that need to be identified and adapted to the specific needs of the nation. This is no easy task at hand, as there is no magic solution for a nation's development, but rather an assiduous work of comprehension and adaptability. In an increasingly changing economic environment, constantly influenced by the decisions and actions of a large variety of actors, the government intervention can improve the welfare of society. In the same time, the government is in charge of identifying the critical factors that cause the volatility of the markets and, implicitly, the government's responsibility is to provide possible state policies that meet such situations.

In this context, Romania is a nation that lacks a healthy planning and a long-term vision. Romania has come a long way, but its path is somewhat paradoxical when referring to its economic growth and respectively its development. The country has registered a significant increase in its GDP; however, the country's population does not perceive

any changes in the quality of life, quite the opposite. Trying to understand the root cause of this, other factors, which influence Romania's economic development stagnation, come to light. As such, we see the economic growth of the country dependent on consumption, but not on the internal production. Furthermore, we see a deindustrialized country that struggles to boost its GDP by augmenting its public debt, but not by focusing to invest in infrastructure, in education or research. This bleak picture, calls for action. Romania is in need of a long-term strategy and vision, and strong leaders that ground their thinking and decision making process on factual data, and not on assumptions or perceptions.

There are not always easy and clear-cut solutions when dealing with the issue of economic growth and development, and each school of thought comes with its strengths and shortcomings. Nevertheless, the approach of governments should be one of in depth comprehension and analysis combined in a balanced strategic mix adapted to the country's specific needs. From the role of innovation, education, infrastructure to the more complex production capacities, they all have a direct impact in the economic development of a nation in different degrees, depending on the specific characteristics of every one of them.

Abstract. *In a time of disruptive innovations, the public services cannot remain untouched. The old political slogan “do more for less” seems to be more real than ever. In this context, digital transformation becomes a change path with huge dynamics from the stage of Digitization, over the E-Government stage towards the Digital Government one. The organization of future will benefit from a DevOps flexibility and capability in a geo-informatics system (GIS) which will offer an environment open to innovation, open to new solutions by storing, processing and analyzing different kind of data, including the spatial data. Our main contribution, based on the new policies streams on the background of digital disruptive technologies is that Romania’s transformative process toward digital governance has to take in consideration the location intelligence and develop also the local e-governance using spatial data.*

Keywords: *Digital transformation; local e-governance; disruptive innovations; GIS; DevOps.*

Introduction

Diverse and disruptive economic, social and environmental challenges request innovative policies and strategies for action. Digital transformation becomes a changing path with vast dynamics from the Digitization stage, over the E-Government stage towards the Digital Government one (OECD, 2016b, p.57). The Digital Government is focused on openness, transparency, engagement with and trust in government based on new strategies to create public value (OECD, 2016b, p.57).

Software development allows the freedom to choose and the flexibility to implement the right tool for any organization, from the project management in Agile solutions (a specific software development methodology) to a broader spectrum, covering the entire organization, like in DevOps software development method (RedHat, 2018). The activities of modern organizations are based on communication, collaboration, continuous feedback, experimentation and integration, the result being a new work environment provided by the partnership between software developers and IT professionals.

Ubaldi (2013) defines the Open Government Data (OGD) as a philosophy - and increasingly set of policies - that promotes transparency, accountability and values creation by making government data available to all. Brokx (Geospatial World Magazine, 2018, President Imagem Benelux) points out that technologies, people and governments merge in the location intelligence: "location intelligence merges with multi-source data and with other IT systems in order to produce concise and streamlined solutions. It is no longer considered to be used only in geospatial domain; rather it is used as a building block to solutions". Both time and location are the ubiquitous characteristics of any data. All new technologies IoT, deep machine learning, robotics, and Artificial Intelligence depend on data. Alla (Geospatial World Magazine, 2018) estimates that geospatial is the future backbone of the "smart habitat". The Research Institute for Environmental Systems (ESRI, 2015) found that since 1980, even if the technologies and the formats have been changed over the years, the data categories have been and still are significant: administrative areas, cadaster, street networks, utility networks and environment. Crampton (2004, p.49) found that GIS is part of governmental rationality, while "the human distributions across a territory are particularly central to politics". Barr (2006) sees that e-government involves GIS because the relationship between the government and the citizen is frequently geographically based. Lieven (2017) points out that much of the success with GIS does not originate in technology implementation, but in the ability of building a location capability. In this line, Hernando & Olmedo (2015) present Pere IV as an old industrial axis in the city of Barcelona, transformed in a smart city using collaborative technologies – community governance.

In this context, we try to investigate the challenges and opportunities regarding Romania's transformative process towards digital governance taking into consideration the location intelligence and also developing the local e-governance using spatial data. We try to highlight the need to a digital transformative path for e-government local services and to assess the leap we can do to transform our public services using new technologies in order to provide better information, better solutions customized to the client at his location.

The dynamics of the Romanian e-government services

In 2016, OECD (2016a, p.18) concluded that Romania's performance is "more closely aligned to the European average in terms of digital government development", but "the tendency since 2010 has been negative, not because Romania has stopped progressing, but mostly because other countries progress at a faster pace and in a more sustainable way." (OECD, 2016a, p.19)

Didraga and Brandas (2015, p.74), Didranga (2015, p.28) conclude that e-government 2.0 projects in Romania need to increase their impact and efficiency. Filip and Stoica

(2008) signal the lack of computer and Internet usage abilities, fact confirmed by Stoica and Filip pointing out that “the public service interactions via Internet is negligible”. Gatman (2011) points out that e-Government success in Romania is conditioned by three equally important and complementary dimensions: financial, human resources and policy. Matei and Gaita (2015, p.983) found that the feature of the management process of public services in Romania is the functional hierarchical subordination. Matei and Iordache (2016) found it important to increase local autonomy, indicating that the e-Government at local level is not a priority yet. Vaduva (2016) considers that the success of the public administration reform in Romania is conditioned by the curbing of corruption and by the generation of economic prosperity. Vrabie emphasizes the paradox for Romania: pioneer initiator of e-service projects (Virtual Payment Office www.ghiseul.ro since 2006, e-voting method testing since 2003, e-Procurement system (www.elicitatie.ro) since 2002, e-guvernare.ro launched in 2003), but having a population not connected, mainly because of two barriers, workplace and organizational inflexibility along with digital divides and choices.

Connecting policies to reality and more precisely to spatial reality, in a research employing GIS analytics, Lincaru, Pîrciog, Grigorescu and Tudose (2018) show that “both Digital Agenda 2020 and the Administration strategy are strongly correlated together, but they are not harmonized with the high human capital policy, even if there are objectives strongly dependent on this category. The acquisition of digital skills for the tertiary employees in public administration is a priority.” Also, another result of this research shows that “in public administration the high human capital is clustered in a few innovative hubs, which in the absence of a functional and interconnected national administration IT system makes impossible the democratic governance act, especially in the context of regional decentralization.” Another interesting insight of this research is the solution proposed to develop “remote intelligent public services in a customized way, tailored for the local problems”. There is a visible spatial correlation between the Low-Low (LL) high human capital clusters and marginalized location as well as low or absent broadband infrastructure coverage.

In this context, the level of development for the local e-government reform and the digital transformation of the traditional public services are questionable and the building of a new paradigm of thinking is needed.

Building a new approach of the local e-government services

The need for spatial data and location

“E-government, as a new administration model, aims at increasing government performance and efficiency by using the latest technologies in the transaction of information, science and goods among government agencies, citizens and private sector.” (Geymen & Yomralioglu, 2008). To this definition we add the transaction level that can be: national, regional and local. The e-government services are based on the digitization of public services. In general, e-government applications use non-spatial data, while only a few applications using spatial data (web based GIS) are related to the Government agencies in Romania. GIS applications will become more and more developed in the future because agencies use more and more spatial data. According to the same above mentioned authors, there are two types of GIS applications for spatial data on which e-government applications using internet are based. The first type is

online and interactive maps using spatial query, address search, route analysis, buffering, and overlaying analysis. The second type of web based GIS application is transmitting the spatial documents of various agencies (cadastral administrations, local governments and forestry, mining, water managing agencies etc.) to their clients over the web.

As Barr (2002) said, when a citizen accesses government services via internet, it creates a separation between the place and the public service. In this view, we need tools to re-establish that connection. These involve frameworks to identify individuals and places. Such geographical referencing framework is GIS. In order to reduce inequalities and to offer democratic e-public services to all people, considering that social exclusion is both an individual and a geographical phenomenon, we highlight the geospatial dimension in the treatment of any kind of data. In general, deprived areas accumulate more economic and social problems which are a characteristic to certain groups of people and places. The process of creating the spatial data must be regulated in order to ensure consistency, non-duplication and timeliness. In fact, we can involve GIS in e-government services because the relationship between the government and the citizen is in many cases geographically based (as we mentioned above). Barr (2002) found that "geographical information is a vector of e-government information resources and its application contributes to integrating government information and to promoting public service."

Challenges to successful digital transformation of public services

In many countries, the initiatives of the local government are only in the initial stages of the development of e-government services and they face some challenges concerning their ability to provide high level of e-government services. In a study of Chen & Gant (2001), an inadequate IT infrastructure, the shortage of IT workers and the lack of financial resources are the main relevant barriers to e-government.

In fact, most of these challenges relate to human dimension and concerns about the privacy and security of personal data. The challenges for decision makers regarding the stages of the digitization projects relate to practical issues such as funding, design, development, testing, implementation and assessment. Another challenge is to accept that in practice the speed of advancement in technologies exceeds the speed with which the potential benefits can be obtained in the provision of public services (OECD, 2016b).

The same OECD study emphasizes that the new steady integration of new technologies (such as cloud computing, social media, mobile technology) into people's everyday lives, businesses and governments is challenging and gives rise to an ecosystem of public engagement and relationships that are beyond public, private and social spheres. The same conclusion is sustained by Garson (2006), who mentioned that through e-governance, government services are provided to citizens in a convenient, efficient and transparent manner, although there are three groups interested (government, citizens and businesses/interest groups) there do not have distinct boundaries.

The new digital environment offers opportunities to rethink and to reposition the relationships among stakeholders (citizens, business and nongovernmental organizations), counting on collaboration, reshaping political priorities, participating in the design of public services in order to deliver coherent and integrated solutions for

these complex challenges. The governance approaches are changed and it is necessary to shift from government-centered services, anticipating citizens and business needs (user or citizen-centered approaches) to the last stage in which citizens and businesses determine their own needs and address them in partnership with governments (people or citizen-driven approaches) (OECD, 2016b). In this context, the local dimension of digital government services is very relevant, as it is in the center of digital transformation.

Internalize the process for the digital transformation of public services

The actual e-government services are not able to satisfy at high quality and standards the needs of the State – administrative services or of the public – direct personal services (Eurostat) either. The Romanian e-government organization needs to be (re)constructed. For this purpose, the current Romanian public organization has to go through a process of digital transformation. E-government is not just about websites or email and SMS. It is about how business organizations change in relation to public services and vice versa. That means to develop two stages in transformation. The first stage means greater use by governments of digital technologies in order to improve data management, obtaining more efficiency and productivity of end-user delivery. Digitization of public services means new delivery methods to reduce costs, both for administrative service or directly, by standardization of personal services. Administrative services are those functions delivered to governments and Direct personal services are services delivered to collective or individual users addressing needs (to the public services) of well-being and of social and economic development. The final objective or stage of the digital transformation path is “Digital Government”, “enabling governments to create increased public value using more and more openness, transparency, engagement with and trust in government through the integration of digital technologies and user preferences in service design and delivery of direct personal services and in shaping public policy outcomes, while also achieving efficiency and productivity gains” (OECD, 2016b).

E-government delivery models can fall into the following categories: as Saugata and Masud (2007) said, “e-governance is the application of information and communication technology (ICT) for delivering government services, exchanging information, communication transactions, integration of various stand-alone systems and services among government-to-citizen (G2C), government-to-business (G2B), government-to-government (G2G), government-to-employees (G2E) as well as back office processes and interactions within the entire government framework.”

The disruptive technologies and local e-government services

Disruptive innovations are related to new business models that break traditional practices. Such models typically combine a disruptive idea with a technology that pushes the innovation forward to unexpected capabilities. Disruptive innovation offers a “proven path to accomplish this goal” and can be a good leader in the transformation process of public services (Deloitte, 2012).

But how can a traditional public service organization be penetrated by disruptive technologies? At first stage, we must develop a hypothesis by exploring the dominant clichés in the area in question and then inverting or denying them (Williams, 2011, p.17).

Disruptive innovations generated by digital technologies not only generate competitive advantages, but they create organizational capital, they create new business models (Anderson, 2014). In the second stage, we must protect the whole environment created from the regulatory and the ancient rules and procedures, if these new disruptive technologies begin to penetrate the organization, in order to protect them.

Now, a question occurs: how important is "location" for disruptive technologies? The location is analyzed by means of Geo Informatics System (GIS) - an informatics system delivering Demographic Analysis, Emergency Preparedness, Land Management and others. If "everything" and "everyone" is "somewhere", does GIS not become critical to the new business models? What if location stopped being an add-on, but rather became central to new paradigm of thinking?

In this context, we already have the components of a system and each of these components has high capabilities and flexibility and the next step is to (re)build the public organization, so that we can provide local e-government services at best quality and highest standards no matter where the location is.

The need to (re)build the local e-public organization - emergence of DevOps in GeoInformatics

In operational terms, Romania has to achieve the construction of the e-government network, launch e-government-oriented geographic information technology service and advance the construction of the e-government geographic information platform.

To transform the public organization means to rebuild its culture, so that this transformation should be sustainable. This change must be made by considering three components of the IT system: development, operations (DevOps) and GIS. The geographic information application significantly advances the technological progress of the government administration offices. According to Meng et al. (2014), "the informatics achievements can be submitted via unified geographic information platform in order to meet business management needs and with a view to forming a multi-sector and a multi-system collaborative service prospect."

The most important dimensions in this digital transformation are:

Philosophy: DevOps is a culture that unites all the layers of the IT organization, people, process, operations and technology. It shortened the version of the term development and operations. DevOps is not an IT solution. It is about a holistic approach of the technology and management and it means it is used as it develops. DevOps is appropriate and harmonizes with the whole concept of local e-government. Local e-governance is related more to the open source. Open-source code is meant to be a collaborative effort, where programmers can improve the original design and share the changes within the community. **Enterprise Culture:** DevOps encourages feedback from users and the products can be re-evaluated in real time

Management: Workflow optimization and automation take place to the highest possible extent by standardizing processes and documents. Communication and collaboration are a huge priority and the cross-communication, constant learning and improvement-centered approach as well. DevOps are related to open source that assures the flexibility

to implement the right tool for your organization. Also, Dev-Ops allows incremental iterative approach leading to efficiency. DevOps includes all the manners of better learning.

The effective cooperation among different in-house departments of the local administration, by integrating and interconnecting services and processes that take part in common transactions (Koussouris et al., 2007).

Funding: In the long run, DevOps helps organizations save money by using technology that is typically expensive. Another important aspect is the value of open-source information that is essentially free.

Resources: In the DevOps concept, the teams are not so distinct; the cross-communication is beyond the organizational structure. In DevOps they bring together the development engineers and the professionals in the organization. DevOps allows government to deliver cutting-edge platforms and services to the public faster than ever before (Redhat, 2018).

Building and configuring technology architecture: The applications using integrated platforms are capable of unlatching disruptive forces in the development of the business system and especially in the traditional manner for solving issues in these business models. Taking configured and built re-development as major developing mode can rapidly build diversified application systems in GIS field. (Meng et al., 2014). Another important resource is the cloud model (Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS) which offers its own specific features and functionalities and it is crucial for the organization to understand the differences. Cost reduction is one of the main reasons for moving to the cloud, but it can be achieved having the right plan.

Large cloud data centers are able to provide huge savings to companies; for instance, the cost of storage at a medium sized data center is \$2.20 per gigabyte (GB) per month (Pawlish & Varde, 2018).

Emergence of DevOps in GeoInformatics: A significant trend in the DevOps is the rise in modular approaches to system building. It is better today to work with small and agile teams to manage customized applications instead of monolithic and big applications where huge teams work. Pawlish & Varde (2018) emphasize as an important advantage that smaller teams can “develop the software and operate in the external environment simultaneously”.

New type of relationship between the public organizations: e-public services are forming architecture and it will be a need for sharing information across vertical and horizontal boundaries of government organizations and for a balance between centralized and decentralized information sharing (Yang, Pardo & Wu, 2014).

Public services, in general, are less open to changes, but the digitization stream, the magnitude and the penetration rate of the new technologies put pressure on the public services to accept the digital transformation and the others changes that are about to come.

Addressing challenges to providing local e-government services - e-government IT outsourcing

If DevOps requests a significant cultural shift, e-government IT outsourcing may be another way to help local governments overcome barriers such as shortage of skilled IT personnel, limited financial resources and poor IT infrastructure. At first, local governments must choose an e-government IT outsourcing model. According to Chen and Gant (2001), there are some conditions that favor the decision to use this service and are related to management support, promise of large efficiency gains, enough IT capability, less burdensome outsourcing rules and procedures and a variety of high quality and reliable outsourcing IT public services. These application services respond to the level of government involvement at local level. Small local governments of cities have a few employees working in their IT department. In this case, an outsourcing e-service provides a source of IT talent pool for the development and maintenance of high-performance e-government applications that can serve a lot of small local governments. These kinds of services have a lot of staff, pay competitive salaries and provide strong IT infrastructure needed to support e-government. The use of the outsourcing IT e-services is beneficial because they take advantage of the economies of scale.

Using this kind of e-government services could represent the first stage of the digital transformation, but that depends on the local government strategies and on the decisions of the local authorities.

The increasing role of social media

In the latest years, the increasing of social networks such as Facebook and Twitter proved that the citizens are now much more involved in decision-making processes. This kind of involvement can contribute to the development of the local e-government services. The social media analysis helps understanding e-government services in different development stages and in different locations. This kind of engagement by citizens improves the transparency and the trust in governments. By providing empirical evidence, Song and Lee (2015) demonstrate that social media is effective means for government to improve citizens' trust in government by enhancing their perceptions of government transparency.

Conclusions

In the digital agenda in Romania we can adopt a new stage of e-government development and draw up the most courageous policies and actions based on a new approach of the local e-government services that can help us overcome the actual state of things using some best practices in domain. In the digital transformation of Romanian local e-government organizations it is appropriate to adopt the Dev-Ops in a Geoinformatics system (GIS) approach, which allows incremental iterative approach leading to efficiency and provides flexibility of resources and local capabilities delivering high quality public services.

Another way to step forward is to adopt an E-government IT outsourcing model which helps local governments overcome barriers such as shortage of skilled IT staff, limited financial resources and poor IT infrastructure. This idea is sustained by Lincaru et al.

(2018) research proposing to develop “remote intelligent public services in a customized way, tailored for the local problems”.

At first stage in the digital transformation, using intelligent hypothesis and making from location a central public service approach connected to open source, we can transform the Romanian local e-governance into one that is efficient, transparent, trustful for clients and able to provide high quality public services.

Failures in implementing local e-government services occur, but they have nothing to do with the technology or with the applications of technological innovation themselves, rather the organizational and social aspects that are still missing in the design, implementation and adoption of those services. (Chen & Gant, 2001). In the context of new and penetrating technologies and of a diversity of public demands, it is a need for a culture of flexibility and a strong public organization management to deal with dynamics, with imbalances and with non-linear process, with initial resistance, with workplace and organizational inflexibility in order to be able to ensure the cross-communication and cooperation within an ecosystem of public engagement and relationships that are beyond public, private and social spheres. In this case, in Romanian public service organization this challenge will be a huge one.

As social media becomes ubiquitous, Romanian local public services can exploit the resources of social media by developing and monitoring the different stages of the local e-governments digital transformation and development strategy.

GLOBAL URBANIZATION AND THE NEED OF SMART CITIES DEVELOPMENT

Cătălin VRABIE

National University of Political Studies and Public Administration

30A Expozitiei Blvd., sector 1, 012104 Bucharest, Romania

catalin.vrabie@snsa.ro

Abstract. Nowadays, more than half of the world's population is living in cities, and by 2050 this percentage will rise up to 66%, according to the World Bank. These dynamics will bring important changes in the size and role of cities. The fast-growing urbanization will lead to an increased level of water, energy and fuel consumption with a significant impact on biodiversity. Cities are also important contributors to climate change but in the same time they are also vulnerable to it – the newspapers are often presenting articles regarding strong storms, heavy rains, extreme temperatures that affected life in cities around the Globe. This is an effect of urban development. However, the increased level of human concentration brings benefits too: an increased demand for cultural activities, education, and mobility, which can lead to an increased access to jobs, longer life expectation and so on. Cities – no matter how small or big are they, are very dynamic. They rely on people and resources. The article intends to present the cities needs to meet the economic and social aspirations of their inhabitants by presenting both the literature perspectives as well as few case studies we have found in Romania and in the world.

Keywords: smart city; IoT; technology.

Introduction

According to the United Nations and the World Bank global statistics, more than half of the urban population lives in cities with less than 500.000 inhabitants, and just one eighth lives in cities bigger than ten million inhabitants (London, Tokyo, Mumbai, Shanghai etc.). However, the highest growth rate is to be seen at cities with a population between 500.000 and 1.000.000 inhabitants – especially in Asia and Africa (United Nations, 2017; World Bank, 2018).

The fast-growing rate of urbanization and the unplanned expansion of cities today bring huge changes for the economies – at all levels: city, country or even region. If we are to speak only about the water consumption, fuel, and electrical power, we can imagine the high growing level of pollution – a phenomenon that strongly impacts the lives of citizens, climate, and environment. Even if only two percent from the Earth surface is covered by cities, they consume about 80% of the energy that is produced by the whole world and, even more, they produce 75% of carbon dioxide emissions (United Nations, 2017).

By that, we can easily say that even if cities are the most vulnerable entities to the climate changes for example, they are the most responsible for that too. Some of them are affected by the increased winds power, big storms etc. while others might be affected by extreme temperatures – above or below zero. All those elements do have the power to alter the quality of life of their citizens. In addition, many cities do face issues like

poverty, lack of housing – things that are easily associated with crimes. The pressure on the public safety system or on the health system is huge (World Bank, 2018).

Cities from the developing countries are facing the strongest challenges. Here, the statistics show a very fast growth rate of the urban population – 95% till 2050. Although those cities are poor, with insufficient resources and a low level of administrative capacities, their citizens will face very strong challenges. Almost one billion people live in slums – at the limit of subsistence, slums that are located inside the borders of big cities (UN-HABITAT, 2012).

Figure 1. Most affected areas by the increased number of the inhabitants by 2050
(Source: The author after UN-HABITAT reports for 2012)

Although big cities are facing issues like those we already mentioned; there are few benefits as well. The pressure on the social services will force them to get improved, the number of hires will start to grow, and there will be an increased number of cultural and social activities. The same will be recorded regarding educational activities, mobility, public health and so on. In other words, we can speak about an increased life expectancy and a poverty reduction.

Cities are very dynamic entities that work mostly on the continuous flow of people, ideas, resources and, generally, their links with other entities from the surrounding environment. To prosper, cities should answer to the economic and social demands of their inhabitants. Cities should manage their impact on the environment to ensure a sustainable growth from which everybody to benefit.

Rio de Janeiro – an example of adapting technology to the needs of the inhabitants

Rio de Janeiro, the second city in size from Brazil, with a population bigger than seven million inhabitants, is a city full of life, but, as most of the world metropolis, it is facing major challenges in its development such as high number of criminal acts, old infrastructure, poor social services and so on. On top of that, being located on the Atlantic coast, quite often it is facing floods and landslides due to the high mountains of the surroundings. All those issues have the tendency to get even worse due to the climate changes. The slums from the suburbs are built on the mountain hills from the

surroundings and, by that, they are the most affected by those natural disasters (UNICEF, 2012) – heavy rains destroyed many times those highly populated areas making a lot of victims and demolishing a high number of houses.

To fight with those issues, and taking into consideration the fact that Rio was hosting two major sports events in the world - The 2014 World Football Championship and the 2016 Summer Olympics, the mayor of the city, Eduardo Paes, established a City Operations Center. It was built by IBM, and it started to run from 2010 – long before 2014 because such projects need time to produce effects. The Center is coordinating activities of over 300 agencies and city departments, plus those of the private companies – for transport, health, sanitation etc. integrating them into one single command and control system.

Surveillance cameras placed all over the city send info in video or photo format to the command center, images that are played back on hundreds of screens – from here the whole activity of the city might be seen. For analyzing traffic and avoid risks as traffic congestion or road incidents the center uses software applications designed especially for this purposes (the statistics made by it – with the support of big data collected over time, is the key of a fast and correct decision). Another software application, this time designed to analyze the climate changes and the sea level, is able to anticipate two days in advance the risks of flooding and areas where those risks might appear. This info helps the municipality to route police forces, ambulances and intervention teams, and by that being more close to the citizens and their needs. Of course, being known that prevention is more efficient then intervention, the authorities make use of technology to alert citizens in danger – closing the streets that are under risk or even by sending phone messages to citizens who, by the way, they have free access to the surveillance cameras in order to see and analyze by themselves the evolution of the variables that might put them in danger.

Those technologies are not the only one used by the city of Rio de Janeiro. In contrast with the huge investment made for the City Operations Center, young citizens are using the mobile technology in a very creative way. They attach smartphones to kites and then fly them over the slums and waste dumps in order to collect photos that are used to map those areas. By that, they manage to find out the areas that might be affected by landslides or electric poles that are at risk of collapsing and so on (UNICEF, 2014).

The characteristics of a smart city

The challenges that cities today are facing the future are completely new. This also provides a framework for collaboration and development among citizens and organizations to find solutions over the new technological opportunities. In smart cities, creativity, innovation, and entrepreneurship, together with smart technologies, are the ingredients for developing new solutions for their citizens.

As we saw already, there are two different important approaches to meet the smart cities concept: top-down and bottom-up. The top-down projects are usually big projects that imply huge investments - the City Operations Center in Rio de Janeiro for example. Bottom-up approaches, such as Rio's young people's initiative to use mobile phones attached to kites, are cheap solutions, at the citizen's fingertips that puts them both in the middle of the problem and the solution found.

Nevertheless, there are also situations in which smart solutions are not sustainable - when the development of technological solutions has been made for the sake of the technology itself. The city officials usually accept the technical challenges without really understanding what kind of problem they are addressing, having a rather superficial image about the concrete needs of the citizens. These solutions are, in most cases, the result of research by major IT companies that obviously want to sell their products. Due to the fierce competition on the market, it is quite difficult to find the relevance of a product in real life. There is often not enough time for the population or administrative environment to assimilate the solution found when it is tested during the pilot phase.

Other cities regard smart technologies as a universal panacea. They believe that the location of sensors all over the locality, electric cars, smart grids or the existence of an operations center will solve all the problems. Although they have not configured clearly the purpose of the smart technology, they choose to implement this type of solution simply because they are functional elsewhere. Prioritizing the actions of the public is a very important element in the sustainable approach to the development of a smart city. First of all, the problems of the community must be identified, and then it will be decided whether the solution really resides in smart technologies.

In developing smart city strategies, there is a need for vision - both in terms of planning and management - for smart cities to evolve sustainably and harmoniously. The Rockefeller Foundation, through its 100 Resilient Cities (100RC) program, devotes its efforts to help the world's cities become more resilient to the 21st century social and economic challenges. 100RC Experts describe resilience through its four dimensions (100 Resilient Cities, 2013):

- **Health and well-being** - this dimension takes into account all those who live and work in a city and not just its citizens;
- **Economy and society** - social and financial systems must allow the urban population to live peacefully and to act collectively;
- **Leadership and strategy** - these are the processes that promote effective leadership and inclusive decision-making for integrated planning with the involvement of all actors in the social, political and business environment;
- **Infrastructure and the environment** - this dimension concerns the resilience of a city through artificial and natural systems that provide critical services, enabling the flow of goods, services, and knowledge while protecting city assets.

If smart cities want to address the challenges they face, the most important step is to involve all actors (public administrations, private companies, universities, public service providers, non-governmental organizations and members of the local community) for discussions. Together, they need to explore the complexity of their problems and get involved in the decision-making and strategic planning process of the city they operate in. Only after these discussions, the councils will understand the problems of the city, allowing them to explore through the variety of solutions in the idea of identifying the best of them - which, indeed, could have an important technological component.

The city as a system of systems

In 1960, American mathematician Edward Norton Lorenz introduced, in the theory of chaos, a new theory called The Butterfly Effect. According to this theory, a small change in a system can cause great changes in its later state (Elaydi, 2007). For example, a town can reduce the number of polyclinics in an attempt to concentrate resources on hospitals, increasing their capacity. However, this decision may lead to an increase in the number of cars driving to and from the medical centers now placed at a bigger distance. The effect might be an increase in the number of traffic jams on the city's boulevards, which would lead to pollution that would eventually affect the health of the population in the city. Here is how a decision to raise citizens' quality standards and standards of living could, in fact, lead to long-term adverse effects.

Cities are very complex entities - they are often presented in literature, metaphorically, as living organisms (Magnaghi, 2000). They involve the existence of many interconnected systems, including energy supply system, drinking water, and sanitation, health, food, economic, transport, educational, cultural and much more. This network of systems, products, services, and people flows can be described as a system of systems.

Departments within the local government institutions often collaborate, in private, with service providers (whether private or public) when trying to solve the city's problems - local public transport service providers only collaborate with the transport management departments within the mayoralties, energy providers only with the specialized departments of the public administrations. In the same way, the drinking water distribution system is only connected to a similar department within a particular public institution and so on. In reality, however, the problems faced by these sectors are interconnected, interdependent and, as such, strategies need to be integrated. Only by that, it will be a certain benefit both for the systems themselves and for the recipients of the services they provide (e.g. citizens).

The systemic approach - an instrument in the management of complexity - is the one that can provide students with information on how to address new and complex situations usually placed in uncertain environments - situations that are difficult to understand and manage, being, obviously, difficult to solve with simple solutions (Checkland & Scholes, 1999; Checkland, 2000).

How does the systemic approach work? As we have already figured out, a system can be defined as a set of interconnected components, all serving a common purpose - in a more familiar approach, their efforts must be concentric.

Here is an example: Supposedly, a team of transport experts wants to remodel the transport system in a city - a system that developed unplanned and has been amorphous over the last hundred years. Inherited infrastructure is based on the traditional model of transporting people as being the primary objective of the transport system - which we all know today as being a wrong approach. In a smart city, the objective is citizen mobility - the ability to connect them, in an efficient and elegant manner, with their points of interest.

One way to explore the components and attributes in a system is to plot diagrams to symbolize their interaction or, for very complex systems, to make three-dimensional

models with mobile components (similar to a Lego game). This method helps to understand the complexity of a system, managing to portray it either symbolically - in the first case, or on a small scale - in the case of a 3D layout. More and more often, three-dimensional layouts are also made digital (eventually 3D printed), so it is possible to analyze each element and not just its major components. In making such diagrams or layouts it is advisable to involve all the actors involved by delegating experts to the respective research and development areas. Only in this way can the system be fully understood.

Brasov – one of the best Romanian examples of Smart City

The city of Brasov, placed in the center of the country, is surrounded by mountains, is a very attractive touristic destination both for Romanians and foreigners. The metropolitan area of the city has, according to Romanian National Statistical Council (NSC) is about 400.000 inhabitants making Brasov the 7th most populous city in Romania.

In order to manage the touristic flow as well as its own population and industry, the municipality invested in different management systems that generally might be seen as a City Operations Center. Bellow, we will describe few of the subsystems that are integrated within:

“Integrated Technical Dispatch for the Municipality of Brasov – Geospatial Electronic Services” is built to help the citizens of Brasov to signal any urban problem that they may encounter:

- On one hand, there is a unique phone number. by which the citizens might get in contact with human operators in order to describe the problem that they might have encountered on the public domain (i.e. an infrastructure failure);
- On the other hand, citizens could place a pin on a map on the municipality Web portal, by themselves, to signal the problem that they might have been encounter.

Another component was developing an infrastructure platform for exchanging data among public utility companies. Implementing this had the following stages: Problem analyzing, Design, Developing, Configuration, Software integration, System testing, Implementation, Users training.

The Technical Dispatch is functioning as an informational and decisional hub made to collect information coming from different systems managed by Brasov city hall (e.g. video monitoring system, public lighting system, semaphore management system, GIS, e-documents management, ERP systems) and from those belonging to the public utilities companies, as well as to provide information to private and public institutions expected to deal with security issues (e.g. Police).

The Call Center component is actually an automatized phone system build for citizens unable to use the Web platform, to provide them with the information they need.

The Geoportal subsystem consists in an interactive map – made with an accuracy of ten centimeters, for citizens, to pin the urban problem they face as well as for displaying the problem status. It allows a proper information of citizens regarding the urban problems, as well as, it is allowing them to report any malfunction or service delivery delay.

Another factor we should not ignore is that the software provides a transparent communication channel environment throughout the Brasov citizens by showing them short notices about the repair/replacement or any other working activity needed for resolving the issue.

The Geospatial Electronic Services Delivery subsystem is bridging successfully utility companies with other partner institution, by allowing a fast endorsement for problem troubleshooting and intervention on the public domain. The requests are filled in online, and sent to all the actors involved, together with all the information needed for a prompt intervention (e.g. specific geographical position).

The Business Intelligence Reporting subsystem was developed in order to bring together, under the same screen, all the data from every partner, contractor, and sub-contractor who report to the city hall. All this information flow is possible by an easy to use Graphical User Interface who allows all the actors to input data easily and with accuracy.

Figure 3. Business Intelligence Reporting subsystem
(Source: Brasov city hall)

Problems encountered by a smart city

Some cities have a pronounced touristic character, while others are just industrial cities. The first can attract tourists either because of the mountain landscapes, the beautiful seaside resorts or because of the historical importance they have. Industry can attract investors for easy-to-understand reasons. Each locality has its own specificity. Some are closer to become a smart city; while others have as priorities to meet the basic needs of their citizens. Copying a functional model elsewhere has been proven to have a great potential for turning into a failure (Winston, 2006; Haque, 2010).

The quality of life in Romanian cities generally does not stand at the level of Western European or North American cities. But not only there the cities are trying to become smart. Cities in medium or developing countries also look for solutions to grow smart. The results are not, of course, always what they want. They must analyze and evaluate past experiences to prevent failures and avoid mistakes already made. The experiences of India, Latin America or Africa, the problems encountered by them during the development process may sometimes be more useful to Romanian cities than the successes of Paris, London or New York.

Urban challenges such as poverty, sustainability, quality of life are typically framed in the SWAT analyzes, in the weaknesses chapter. In the case of a city, these weaknesses are social, cultural or diversity issues that, for various reasons, are very difficult to solve - if not impossible. As early as 1973, German Horst Rittel, a professor of urban planning at the University of California at Berkeley and the University of Stuttgart, said that the issues that cannot be even defined by the actors involved better should be left to solve by themselves (Rittel & Webber, 1973).

Let's take poverty for example. What would be the solution to this problem at the municipal level? It is closely related to other elements - education, food, economy and so on. In an attempt to eliminate a weak point, the solution to a particular problem often brings at the surface another, perhaps more complex, one - often there is no recipe for

removing a weak point. However, solutions can be found to help ease the suffering of the populations affected by the problem.

In addressing the challenges that a city encounters, it is often necessary to slowly change the structures of society, rather than implementing a momentary technological solution. Changing behavior (and/or mentality - as we often hear it being discussed), the way we live and work, are essential elements in the evolution of a city that wants to become smart. Technology can indeed play a particularly important role in facilitating these behavioral changes - for example, helping to reduce electricity consumption or changing inter and intra-urban transport methods, but it is not enough. As we have already said along this article, technology is not a universal panacea. It helps solve some problems but does not solve them all. For that reason, the society needs the involvement of its people!

We want to make it clear that cities can be associated with living scientific laboratories, with the participation of all citizens as specialists of the city's lifestyle. They are the only ones who have the ability to explore the problems they face and to find solutions - either with the use of smart technologies or new business models or even complete new public services. Often, following the collection of ideas from citizens, it is possible to develop completely new public policies; new solutions, that would have been impossible to identify from the council's level, can be found. According to the Stanford Summer Arts Institute, the Stanford Design Impact program, strategic thinking is a process that can help cities find viable solutions to solve their weaknesses with their own citizens (IRIS Design Lab, 2018).

Key elements for a smart city

As mentioned above, smart city projects involve the participation of experts from different backgrounds to work with residents in order to help them discover solutions to the issues that they, the inhabitants of that city, consider important.

There is no agreed definition of the smart city concept - although it is generally seen as a smart city a city that uses smart technologies along with data and information gathered/processed by digital equipment to address the challenges it faces.

The fact that cities often make the mistake of starting with technology investments rather than what is important to citizens is also already known (Cushman & Wakefield, 2015). To be successful, a smart project must start with a problem that is about to be solved. We need to focus on the following five elements considered most important in building a successful smart city project (Modi, 2014; Vrabie, 2017):

1. Citizens;
2. Technical infrastructure and data flow;
3. Entrepreneurship and innovation;
4. Strategy and leadership;
5. Education.

Each of the five elements listed above must take into account the following fundamental concepts of success:

1. Sustainability;

2. The use of open data applications - a factor that helps develop smart projects;
3. Protecting privacy and ethics - elements that citizens are increasingly concerned about.

Figure 4. Key elements for a smart city
 (Source: The author after Modi, 2014 and Vrabie, 2017)

Lessons learned

To be successful, Smart cities initiatives should consist in a partnership between the citizens – as the most important actor, business sector, and public authorities. Only by that, it will be possible to be built a solid environment in which information from the public side meets service delivery companies.

Each partner must be responsible for their role and by that to properly interact with the others. Education along with communication is the key ingredients.

weredawioletta@tlen.pl*

Abstract. *The policy for sustainable development for years has been a challenge for local authorities, enterprises operating within agglomerations or urban residents, in the area of ever-higher environmental standards. This is mainly due to the fact that the ongoing process of urbanization of the world, although it is a symbol of social evolution, raises numerous challenges related to intensive energy consumption, overloaded transport networks, water and air pollution, waste and a drop in the quality of life. The implementation of new technologies is currently perceived as a key factor in reducing greenhouse gas emissions, pollution or improving the efficiency of cities. These technologies must be smart, slim, integrated, cost-effective. They should play an important role not only in the field of environmental sustainability but also with regard to the well-being of citizens and financial stability. One of the key areas shaping smart cities, where contemporary technologies should be implemented, is transport. The effective transport operates in well-developed areas. This is one of the aspects of the functioning of urban areas, which is also an element and condition for economic growth.*

Keywords: *intelligent mobility; sustainable development; smart city; management of intelligent assets.*

Introduction

One of the most important socio-economic processes in the modern world is progressive globalization. According to the UN forecasts, it is estimated that by 2050, 66% of the world's population will live in cities. The growing concentration of the population and the innumerable relations between various entities determine a high degree of difficulty in the functioning of urban areas. Therefore, the specificity of contemporary urban centers refers not only to their physical structure but also to virtual networks, connections, and relationships (UN, 2014).

With the progressing urbanization, globalization, technological progress and the growth of ecological awareness and the development of a knowledge-based economy, the search for concepts and models of effective functioning of cities has begun. One of their main assumptions is the achievement of environmentally and socially and economically rational relations between the functioning entities. One of such ideas is smart growth, which task is to minimize the costs and inconveniences resulting from the growth of cities. For some time, technologically advanced cities striving to save resources have been distinguished. Shaping a smart city is a long-term process and requires a well

thought-through way of functioning of its areas, among which are (Sikora-Fernandez, 2013, p. 85):

- 1.Economy (smart economy).
- 2.Transport and communication (smart mobility).
- 3.Environment (smart environment).
- 4.People (smart people),
- 5.Management/governance (smart governance).
- 6.Quality of life (smart living).

City centers recognized as smart cities must, therefore, have appropriate features, the importance of which depends on the direction of development in a given spatial area. Creating smart cities in the above spheres results directly from the postulates proposed by contemporary urban communities that deal with unfavorable phenomena on a daily basis. These are mainly road traffic, noise, security or weakening of social ties.

What is more, nowadays collaboration between self-government bodies and institutions as well as public utilities with internal and external entities, aimed to trigger required changes in attitudes and behaviors and decisions of various target groups, is a reflection of execution of marketing activities (operations, ventures, campaigns). Exchange of values between pairs of units or territorial groups means acquiring specific resources, winning the favor of people and/or approval of offered environmental assets (social, investment, tourist, economic etc.) in return for relatively equivalent assets delivered in a returnable way including material, financial, information and emotional assets. All these activities in self-government units lead to an intelligent way of thinking and create smart societies (Wereda at al., 2016, p.138).

One of the key areas shaping smart cities, where modern technologies should be implemented is transport. It is one of those aspects of the functioning of urban areas, which is also an element and condition for economic growth. Effective transport operates in well-developed areas, equipped with the necessary elements. The economy stimulated by transport generates ever greater needs resulting from the growing production capacities and greater consumption of the society. An efficient transport system often determines the attractiveness of countries, regions, and cities. However, its organization in urban space, where there is a high population density, is an extremely difficult task (Kummitha & Crutzen, 2017, p.48).

Transport problems of contemporary cities

In recent years the development of digital technology is fast becoming a pervasive feature across a wide variety of products. Equipped with the ability to sense, store and communicate information about themselves and their surroundings, these 'intelligent assets' are posed to unlock tremendous opportunities for businesses, public organizations, and individuals, especially for a standard way of living in a sustainable environment (Wereda & Kornec, 2016, pp.133-134).

The necessity of thorough transformations of city structures and public spaces is to a large extent the consequence of many destructive processes that began to appear with the increase in the number of cars. This is, inter alia, the disintegration of cities, i.e. the process of spatial disintegration, suburbanization - the city's development phase consisting in the depopulation of the center, the cost of suburban development, its result

is the development of the entire city transport network and infrastructure development in suburban areas, playing the role of urban dormitories. Along with the deteriorating quality of life resulting from the chaotic development of transport, there is a reorientation of local authorities' actions for sustainable and intelligent solutions not only in transport but the entire urban logistics (Malasek, 2016, p.878). This is one of the main challenges because, as estimated by the Ministry of Environmental Protection, 30% of the total pool of pollutants emitted into the environment comes from transport, especially from road transport, but in cities, the share of transport pollution is much higher, it can be approx. 70 % even up to 90%. In the light of such alarming data, it is necessary to count losses caused by transport, especially those losses that are not suffered by the interested parties, but the whole society (Pajak, 2018).

One of the main problems and still not solved is individual communication. As a means of transport, it facilitates relatively free movement, enabling efficient organization of family and professional life. Being, especially in Poland, a particularly valuable good, a determinant of social position and abundance, many people cannot imagine life without a car (Parysek, 2016, p.12). Entities participating in transport processes, through attitudes, choices, consumption patterns, affect the operation of the transport system. It would seem that the quantitative and qualitative development of road infrastructure is one of the solutions to this problem. However, as many researchers have noted, the concentration of activities related to the improvement of the offer for individual transport leads to a decrease in the attractiveness of public transport. The effect of this is undesirable and excessive demand for further infrastructure investments related to the operation of both individual car transport and public transport (Litman, 2018). This action leads to a vicious circle (Figure 1) including higher infrastructure maintenance costs, environmental degradation, and poor quality of life.

Figure 1. A vicious circle of increased dependence on a passenger car (Litman, 2018)

The car as an element of the spatial development of the city is at the same time the cause of the increase in the city's operating costs and problems faced by pedestrians and city authorities. The size of issues related to the nuisance resulting from the functioning of road transport in the urban space tends to take measures limiting its impact on the quality of life. These projects should be multi-span, focusing on simultaneous

implementation of many tasks to maximize the ability to achieve the assumed goal (Paundra et al., 2017, p.121).

In Poland, this problem is particularly visible. With the entry into the structures of the European Union, our country has become a beneficiary of many subsidies, within which transport infrastructure is being developed. Along with the development in Poland, there are also passenger cars. In 2015, the motorization rate in our country was much higher than in the entire European Union and amounted to 546 cars per 1000 people (in the EU 497 items per 1000 people). Among the largest cities in Poland (over 200,000 inhabitants), the largest indicator is observed in Warsaw, Katowice, Poznań, and Wrocław (Table 1) – data based on the Central Statistical Office in Poland.

Table 1. Motorization indicator in Polish cities with a size of over 200,000 residents in 2009-2016

CITY	YEARS								Growth dynamics
	2016	2015	2014	2013	2012	2011	2010	2009	2016-2009
Warsaw	681	645	620	598	580	565	548	535	21,4%
Krakow	585	557	534	521	503	486	467	463	20,8%
Lodz	525	502	483	466	448	434	408	389	25,9%
Wroclaw	632	300	575	558	540	525	498	487	22,9%
Poznan	660	625	601	578	554	538	514	515	21,9%
Gdansk	572	552	543	523	509	496	475	471	17,6%
Szczecin	508	487	466	449	434	421	400	398	21,6%
Bydgoszcz	549	529	510	500	486	473	462	462	15,8%
Lublin	506	483	463	447	425	410	387	379	25,0%
Katowice	668	632	599	571	540	516	491	484	27,5%
Bialystok	413	394	377	365	355	345	327	315	23,7%
Gdynia	567	542	521	503	484	471	449	441	22,2%
Czestochowa	519	496	489	467	453	442	420	406	21,7%
Radom	471	445	427	413	400	388	371	355	24,6%
Sosnowiec	526	509	495	483	468	453	435	412	21,6%
Torun	490	470	453	441	428	417	403	396	19,1%

The functioning of the car transport is the main reason for the increase in the costs of the operation of urban centers and the problems faced by pedestrians and authorities. The size of issues related to the nuisance resulting from the functioning of road transport in urban space is also conditioned by the quality of moving vehicles. Unfortunately, in Poland, more than half of the passenger cars are older than 15 years (Table 2) – data based on Central Statistical Office in Poland.

Table 2. Age structure of cars in Poland in 2014-2016

AGE OF CARS	YEARS		
	2016	2015	2014
1-3	6,1%	5,8%	5,8%
4-7	7,4%	8,1%	8,9%
8-11	13,3%	13,7%	13,7%
12-15	16,7%	17%	18,5%
16-20	22,9%	22,7%	21,8%

AGE OF CARS	YEARS		
	2016	2015	2014
21 and more	33,6%	32,7%	31,3%

Compared with the new generation cars, old vehicles are much louder, emit more amounts of fumes, and are less safe. The age of vehicles together with the growing motorization rate adversely affects the quality of life in cities. One of the fundamental inconveniences is continuous noise, which the main emitter is road transport, and in turn: air, industrial, neighboring, as well as the noise of mass events.

Data from 2017 from acoustic maps prepared as part of the third round of mapping show a significant exceeding of the permissible noise level in urban areas. The descriptive part of the map shows that in Krakow almost 10%, in Bialystok almost 12%, in Warsaw about 6%, and in Gdansk almost 2% of residents are exposed to excessive levels of road traffic noise (Acoustic Map of Warsaw, 2018; Acoustic Map of Krakow, 2018; Acoustic Map of Bialystok, 2018; Acoustic Map of Gdansk, 2018). However, these results do not reflect the fully analyzed problem. In 2015, research carried out at the request of the European Parliament indicated that dissatisfaction with noise levels is reported by more people than those exposed to above-standard noise (Figure 2).

Figure. 2. Assessment of noise level in selected Polish cities in 2015 (Eurobarometer, 09.04.2018)

The highest percentage of people for whom noise level is a significant problem is in Krakow and Warsaw, where over 50% of residents are dissatisfied with the acoustic climate. In these cities, there is also the largest number of vehicles per 1000 inhabitants. In Bialystok and Gdansk, the level of dissatisfaction is much lower. Białystok is also the city in which the motorization index is the lowest for the group of cities over 200,000 residents.

Another important problem of private communication is air pollution. Cars, next to individually heated buildings, are the main emitter of substances for air shaping the level

of pollution. Among the cities studied, the most people dissatisfied with air quality are in Krakow and Warsaw (Figure 3).

**Figure 3. Air quality assessment in selected Polish cities 2015
(Eurobarometer, 09.04.2018)**

It should be stressed that road transport in Warsaw is the dominant source of air pollution. The communal-living emitters are located on the outskirts, not like in Krakow - all over the city. The capital has a well-developed gas and heating network, to which the vast majority of infrastructure is connected. With this in mind, local air pollution in Warsaw is emitted in 60-80% by road communication (Urbanowicz, 2017).

The problems of noise and exhaust emissions are also conditioned by the volume of traffic, which is growing due to the increasing motorization rate. Traffic load of motor vehicles, of course, is not even for the whole network, it increases with the importance of roads in the functional system and in cities, causing traffic jams. Despite the fact that in recent years the congestion rate for Polish cities is constantly declining, they are still on the list of one of the most congested cities in Europe and in the world. According to the TomTom Traffic Index report from 2017, Lodz is in 5th place just behind Chongqing (China), and in front of such agglomerations as Istanbul, Los Angeles, and Moscow. Congestion on the streets of Lodz results in an increase of travel time by an average of 51%, and during the afternoon rush hours by up to 88% compared to a situation in which traffic jams are absent. In the world ranking in the first hundred, there are seven Polish cities: Lodz (5th), Lublin (34th), Krakow (48th), Warsaw (50th), Wroclaw (63th), Poznan (69th), Bydgoszcz (83rd place) (TomTom Traffic Index, 2018). Despite the fact that the level of congestion has been declining in recent years, it remains at a high level (Figure 4).

Figure 4. The level of congestion in selected Polish cities in years 2008-2016
(www.tomtom.comm, 09.04.2018)

The size of issues related to the nuisance resulting from the functioning of road transport in the urban space tends to take measures limiting its impact on the quality of life. These projects should be multi-span, focusing on the simultaneous implementation of many tasks to maximize the possibility of achieving the assumed goal.

Intelligent solutions in urban transport

Optimization of the transport system in urban space can bring improvement in the quality of life by minimizing external costs and impact on the natural environment as well as increasing road safety. The priorities of the EU transport policy in this respect relate primarily to (Jaroszyński & Chłód, 2015, p.166):

- rationalization of the use of individual vehicles;
- increasing the attractiveness of public transport;
- introduction of modern traffic control and traffic control systems;
- exchange of good practices in the aspect of using existing city infrastructure.

To increase the effectiveness of the proposed solutions, comprehensive models of cities have been developed for many years in which transport and mobility of people is one of the most important links. One such concepts is a smart city.

The smart city concept in the EU documents originally concerned only development in the field of energy and climate objectives (European Initiative on Smart Cities, 2018). Currently, attention is also focused on the use of digital technologies to increase efficiency and improve living conditions, save resources and social activation. The complex nature of this concept causes a heterogeneous understanding of the term.

Selected definitions presented in the literature are defined in table 3. Selected definitions of “smart city” from the literature are presented in table 3.

Table 3 Selected definitions of “smart city”

Source	Definition
Hall et al. (2000)	An urban center of the future, made safe, secure environmentally green, and efficient because all structures—whether for power, water, transportation, etc. are designed, constructed, and maintained making use of advanced, integrated materials, sensors, electronics, and networks which are interfaced with computerized systems comprised of databases, tracking, and decision-making algorithms.
Thite (2011)	Creative or smart city experiments [...] aimed at nurturing a creative economy through investment in the quality of life which in turn attracts knowledge workers to live and work in smart cities. The nexus of competitive advantage has [...] shifted to those regions that can generate, retain, and attract the best talent.
Caragliu, Del Bo & Nijkamp (2011)	A city that is smart when investments in human and social capital and traditional transport and modern ICT infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance.
Nam & Pardo (2011)	A smart city infuses information into its physical infrastructure to improve conveniences, facilitate mobility, add efficiencies, conserve energy, improve the quality of air and water, identify problems and fix them quickly, recover rapidly from disasters, collect data to make better decisions, deploy resources effectively, and share data to enable collaboration across entities and domains.
Lombardi et al. (2012)	The identified clusters are smart governance (related to participation); smart human capital (related to people); smart environment (related to national resources); smart living (related to the quality of life); and smart economy (related to competitiveness).
Bakici, Almirall & Wareham (2012)	Smart city as a high-tech intensive and advanced city that connects people, information and city elements using new technologies in order to create a sustainable, greener city, competitive and innovative commerce, and an increased life quality.
Townsend (2013)	[...] define smart cities as places where information technology is combined with infrastructure, architecture, everyday objects, and even our bodies to address social, economic, and environmental problems.
Scholl & Alawadhi (2015)	smart city (definition) is a programmatic term that summarizes the creation, integration, combination, development, and effective leverage of resources and assets towards innovation, attractiveness, competitiveness, sustainability, and livability of an urban space facilitated and accelerated by the ubiquitous use of advanced information and communication technologies with local governments playing key investigating roles in this process.
Lara et al. (2016)	A community that systematically promotes the overall well-being for all of its members, and flexible enough to proactively and sustainably become an increasingly better place to live, work and play.
Business Dictionary (2018)	A developed urban area that creates sustainable economic development and high quality of life by excelling in multiple key areas; economy, mobility, environment, people, living, and government. Excelling in these key areas can be done so through the strong human capital, social capital, and/or ICT infrastructure.

There are various approaches in the subject literature; various areas of application of modern methods of management and use of technology are exposed. On the one hand, smart city researchers focus on technical and environmental aspects of city management. They emphasize the use and importance of modern technologies in everyday urban life. In the same time cooperation with the business actors are valued (Pinzaru, Zbucnea, & Vitelar, 2018). As a result, innovative transport systems are created, logistics processes are optimized, green and efficient energy systems are created. The authors investigated this aspect of the functioning of cities based on the smart concept in modern technologies recognize the possibility of increasing the efficiency of services and improving the quality of life and reducing pressure on the environment. However, the elements defining the concept of the smart city only in a direct context with information and communication technologies are insufficient. Therefore, apart from the aspect of modern technologies, attention is paid to the role of human capital, education, and creativity in the development of smart cities. Participating management is very important in this respect (Ahvenniemi et al., 2017, p.236). As noted by Caragliu et al., a smart city is when investments in human capital, information, and communication technologies, transport, and infrastructure are carried out through wise and sustainable participative management of available natural resources (Caragliu, Del Bo & Nijkamp, 2011, p.66). Lombardi's social aspect of building smart cities also involves an adequate level of security and preservation of cultural identity. Lombardi describes these elements as "soft factors" for shaping smart cities (Lombardi et al., 2011, p.4). According to the Correia and Wüstel (2018) approach, a smart city is capable of combining physical capital with human capital and developing better services and infrastructure. It makes it possible to combine technologies, information and political ideas into an organized city and services improvement program.

One of the areas of building smart cities is transportation. Urban mobility plays a key role in this process. In particular, these undertakings should take into account the need to maintain appropriate proportions between the social, environmental and economic aspect, constituting the fundamental pillars of sustainable development, which are one of the conditions for shaping a smart city. It is, therefore, an essential element influencing the other areas of the smart city (Sciullo & Occelli, 2013, pp.293–309). The basic goals of smart mobility can be (Bencardino & Greco, 2014, p.47):

- pollution reduction;
- limitation of traffic;
- improvement of traffic safety;
- improving the average speed of vehicle movement;
- minimization of transport costs.

The condition of the transport system in Polish cities is diverse. It results from the differences in the size of cities, in the levels of motorization, in the quality of technical infrastructure, in the rules of organization of transport by public transport, or in the degree of preparation and implementation of transport development policies and programs. An important role in the functioning of the transport system in cities is played by collective communication (Ministerstwo Transportu, Budownictwa i Gospodarki Morskiej, 2013).

However, with the development of technologies and concepts of intelligent transport systems, they are increasingly implemented in Polish cities. As part of the intelligent transport system implemented in May 2015 covering the entire city of Białystok, traffic lights control was implemented at 120 intersections, the priority of passage for public

transport buses, variable message boards informing about traffic obstructions, detours and accidents. Thanks to the above elements, both car drivers and passengers of public transport can now move more efficiently around the city. The system constantly analyzes the traffic and adjusts the functioning of traffic lights on a regular basis. The information from the system is publicly available on a special website, which enables current tracking of traffic in the city and facilitates travel planning. The system collects the above information, determines the traffic forecasts, and on their basis and historical data, it optimizes the management of traffic lights on an ongoing basis. It is a highly innovative solution, assuming a priority for public transport. As part of the construction of an intelligent transport system in Białystok, at the intersections of over 120 CCTV monitoring cameras, the system operator can monitor the traffic situation on an ongoing basis and, if necessary, analyze events based on archived video images (Tomaszewska, 2015, p.326).

In Krakow, the system plays its role mainly in trams, buses, and trains. In fact, it looks like the means of urban transport reaching the intersection send a signal to the central computer, which in turn compares the time of the actual presence of the vehicle before the intersection with the time appearing on the timetable. If a given public transport means is delayed, the green light is extended or lights up faster to allow the vehicle to pass freely. In addition, there are passenger information systems, passenger services, monitoring systems, passenger counting systems, communication systems, etc. in the city. Passengers can use electronic boards at information stops, for example, they see how much time they will have to wait for the bus and what it is its delay. For ITS drivers it means the possibility of informing about currently jammed streets. Information is also sent to operators or security services. Thanks to this, for example, the operator knows about the breakdown of the vehicle before it reaches the stop.

Municipal vehicles are also equipped with central driver or driver modules, which include information for the driver about the level of energy consumption. At the same time, the appropriate application sends information to the operator, who can reward the driver of the vehicle for economical driving. In addition, ITS is constantly supported by the GPS system (Barwiński & Kotas, 2015, p.28).

The "ITS Poznan System" project implemented in the city of Poznan is located in the so-called "western area" of the city (Grunwald and partly Jeżyce districts). Its subject was the implementation of an integrated intelligent traffic management system in Poznan in the western area of the city. The intelligent transport system in Poznan currently covers 115 traffic lights and a public transport fleet of 540 tram and bus vehicles in total. In addition, system users have access to real data about traffic in the city obtained from measurement stations, thanks to which they can more effectively plan a journey through the city through collective transport. The profits resulting from the functioning of this system are primarily determined in the social and economic spheres. The biggest share in the benefits is to have savings due to reducing the costs of the travel time of users. Such profits are immeasurable and it is difficult to estimate their value in money, but the benefits and reimbursement of incurred investment outlays will certainly outweigh its costs (Gawelek, 2018).

The effect of the ITS system implementation is to shorten the timetable times of trams. On the tram from Junikowo loop through ul. Grunwaldzka to the Baltic Sea accelerated by 2 minutes - from 17 to 15 minutes. Also for 2 minutes the travel time from the

Górczyn loop to the West Railway Station has been shortened. In turn, from Rondo Rataje to ul. Półwiejska, at the rush hour, the tram passes by a minute faster, and after the peak - 2 minutes. In comparison to 2016, the punctuality of buses and trams also improved. In 2017, trams went on punctuality 88.79%, whereas in the year before this rate was 81.30%. A similar increase occurred in terms of bus punctuality - 78.23% in 2017 and from 71.60% in 2016. Public transport in Poznan is also more efficient due to changes in traffic organization. (Poznan: Tramwaje..., 2018).

At present, Warsaw has a fairly limited integrated traffic control system covering a small area of the city center. The city also gave up its resources in the past years with funds for its expansion. At the moment, the integrated traffic control system includes Aleje Jerozolimskie, Powiśle, and sections of Wisłostrada. The city prepared a project to extend the system by another 150 intersections, some of which - incidentally - do not meet the current legal requirements for the functioning of traffic lights. However, the idea of developing a traffic control system has not fallen and it is planned to develop it. The analysis is to take into account the latest trends and tendencies in this type of solutions in the world, as well as numerous investments already made in Warsaw. There are several partial or point investments implemented by ZDM, investments are also carried out by Warsaw Trams, which interfere with infrastructure very much, often building signaling from scratch.

Another example of the Polish agglomeration in which attempts are made to implement intelligent transport systems in the area of the Tri-City, where the Tristar system is developed. The benefits of its launch are primarily related to:

- improved capacity of communication arteries in the Tri-City,
- shortening travel times by individual and collective transport,
- reduction in the number of accidents (resulting, among others, from entries at a red traffic light),
- driver satisfaction (lower fuel consumption, time saved),
- satisfaction of residents (more efficient collective transport, the quick finding of a free parking space, reduction of air pollution).

According to data from Gdansk Municipal Investments and the Road and Green Board in Gdansk, buses, trolleybuses, and trams have accelerated by about 9%, but it is difficult to find confirmation of these results in an everyday travel. Even if we compare the upper limits of acceleration, it will turn out that the cars have gained twice as much as communication. The Tristar system allows recognizing public transport vehicles and even controlling compliance with the timetable. However, this did not cause a significant acceleration of buses, because even despite successful tests, priority is given only to delayed vehicles (Sielski, 2017).

An important issue in building intelligent mobility is the skillful shaping of residents' preferences and behavior. This applies not only to the transition from a personal car to public communication, but also solutions based on the principles of economy of sharing in urban transport, such as the use of vehicles (car-sharing) and space in cars (car-pooling). The proper availability of means of transport in these systems in time and space is essential in the dissemination of these issues (Qu, Yu & Yu, 2017, p.686). Recently, the car-sharing service is available in the largest Polish cities. The local and regional authorities of Warsaw and Wroclaw, having experience in the implementation of public bike rentals, analyzed the possibility of introducing urban car-sharing.

However, as it turns out, from the legal side it was a big challenge. At the same time, what turned out to be difficult for local government administration was relatively easy for a private entity. At the beginning of October 2016 in Krakow, traditional car rental - Express, launched a new brand - Traficar, offering the first regular car-sharing in Poland. Traficar originally offered 100 Opel Corsa vehicles available in Krakow (Połowianiuk, 2016). Currently, this service is offered by several entities in the largest cities of Poland, offering its clients more than 2,000 vehicles (Table 4).

Table 4. The size of the fleet of selected car-sharing services in Poland at the end of 2017

Lp.	Operator	Number of cars
1	Traficar	1100
2	4Mobility	330
3	Panek CS	300
4	Vozilla	200
5	Click2Go	100
6	Lubelski Samochód Miejski	25
7	Omni	10

Thanks to the high availability, network coverage, transparent and flexible prices, as well as the availability of cars of various classes, car-sharing fulfills many demands made so far only by private individual transport, thus making it an attractive alternative.

The use of contemporary technologies in the economic, social and environmental sphere can also effectively reduce transport needs using a passenger car. Communication and information technology can successfully replace everyday business trips, official matters (bank, administrative matters, etc.), stationary shopping or personal meetings. Bearing in mind the aspect of "indispensable mobility", local self-government should try to limit the need to use cars with such solutions as better communication, attractive public transport or modern land development (Malasek, 2016, p.878).

Conclusions

Cities, in which undesirable phenomena of high traffic, air pollution, high acoustic nuisance, degradation of the landscape and excessive, chaotic growth of agglomerations exist, are considered unfriendly not only for people but also for the functioning of business entities. Therefore, the management of the urban transport system in the area of people should be an integral part of the urban development policy. The task of local government authorities, in addition to creating economic conditions conducive to the innovation of enterprises, is also taking care of the city's development in the social and ecological sphere. At the same time, it should be emphasized that Poland is in such a moment of economic development that the quantitative and qualitative development of road infrastructure is necessary to create an efficient transport system. On the one hand, it allows for transit outside of urban centers, and on the other hand, it encourages the use of modern communication routes. That is why it is very important to develop intelligent public transport and a system of shared use of cars that efficiently meet the transport needs of residents of urban centers. It should be remembered that each city has its own specificity and the proposed solutions should also be adapted to the conditions prevailing in it. In the field of intelligent mobility, one should remember not only about the need to develop intelligent forms of transport, but also the needs of residents should be taken into account because huge investments in smart technologies

can be made, which will not bring tangible results. An intelligent city transport system is one that satisfies primarily local transportation needs in an economically, socially and ecologically effective way. Modern technologies can only be effective if their users can use them efficiently. Therefore, the priority in the aspect of building smart mobility should be system consultations with residents, in which technologies will play a supporting role.

Abstract. *New public management is gaining momentum in the process of managing the public administration. European countries driven by the idea to increase the efficiency of the public administration impose strategies and a new approach to the process of public administration management. This means independence of the managerial function in the public sector, independent governance, quick response, responsiveness of the public administration and empowering responsibility of the administration. The favoring of the discretionary right inflicts the question of the responsibility of the public administration. This creates new models for monitoring the performance and assessment of the public administration that allows strengthening of the administration's responsibility in all categories of titles, including managerial workers. In the Republic of Macedonia, the new model for public management is difficult to be accepted, regardless of the fact that legislator made changes to the administrative laws in the approach of assessment and accountability of the administration. In the European countries, the new public management is more acceptable as an indication of the fact that in many European countries the central government conveys the function of managing the public administration as an independent function of the local governments. Moreover, the local authorities are free to create payment systems, regulate the assessment process and to motivate the administrative officials. Hence, the subject of this paper is to understand the role and significance of the new public management in the Republic of Macedonia, as well as to make a comparative analysis with the European countries. Hence, this research paper aims to impose an opinion on the significance of the new public management and whether it contributes to the efficiency of the work of the public administration. The research methodology is based on an analysis of research results and strategies adopted by the European countries. In addition, the paper analyzes the administrative laws and bylaws with an assessment of the new public management. The results of the research point to the conclusion that the new public management is not recognized in all European countries, and that the Republic of Macedonia, is not familiar with the new public management. However, basic legal solutions can be explored that leave the possibility for the application of the new managerial management. There is a necessity of comprehensive analysis of the work and development of the public sector in the Republic of Macedonia, the obligation for*

a serious approach of the law implementation and a reduction of the resistance to the changes by the employees in the public sector.

Keywords: *public management; public administration; efficiency; responsibility; results.*

Introduction

The concept of “new public management” has emerged as a solution to the slow and exhausting bureaucratic rules that have resulted in typical public administration inefficiency (Andrews & van de Walle, 2012; Christensen & Lægreid, 2001; Ferlie & Steane, 2002; Gruening, 2001; Pfiffner, 2004; Vienažindienė & Čiarnienė, 2007). The tension between accountability and efficiency has marked the contrast of the traditional public administration and the new public management. Thus, Max Weber's theories are directed towards accountability in the form of bureaucracy, by establishing strict hierarchical control from the top to the lower levels. Woodrow Wilson was directed to a policy dichotomy / civil servants to use effective techniques to make a policy choice. Frederic Taylor was directed to a strict control in the management process (Benz, Siedentopf & Sommermann, 2004, pp.443-454). Through traditional models of policy implementation, the state faced high costs, the inefficiency of administration and discontent among service users - the citizens. Consequently, substantial changing in managing public affairs has emerged as a needed new paradigm. The new approach in managing public affairs, emphasizing control function of the state authorities over the privately owned agents in performing duties of public interest, has the relaxed financial burden to the state. In addition, the “new public management”, abandoning the strict hierarchy in administering public affairs implies transfer of implementation competencies to decentralized administrative bodies and organizations. Thus, Robert Behingo defined public management as “a set of tactics and strategies aimed at improving the efficiency of the public sector” (Diefenbach, 2009).

Having in mind that traditional hierarchical setting and strict control by the top government levels have prevented the administrative entities closest to the end users to deliver their services fast enough, the new concept of public management, aiming public services performance and public satisfaction improvement, advocates for decentralized administration and delegation of administrative authority by contracting privately operated entities using approach of market-driven competition among them (Andrews et al., 2011; Andrews & van de Walle, 2012; Boyne, 2010; Cowell et al., 2012; Ormond & Löffler, 2006). Thus, permanent monitoring and performance evaluation of public services delivery by privately operated entities has become essential for the state authorities (Amirkhanyan, Kim & Lambright, 2008).

Regarding the public administration performance, the following questions are essential:

1. What should be done: who will control the policy implementation?
2. Who will be the immediate policies implemented?
3. How the administrative effectiveness and public satisfaction will be measured?

To face all these questions, it is necessary to establish a balance between accountability and efficiency. If the administrative accountability is in the focus, the evaluation will be related to the administrative procedures applied according to the strict criteria of hierarchical control. If the administrative efficiency is in the focus, strict hierarchical

control will be replaced by a delegation of authorities, emphasizing monitoring and evaluation of public services delivery by private agents. The concept of new public management is aimed to overcome the problems caused by strict hierarchical control typical for traditional public administration, turning instead to a delegation of competences, greater flexibility and room for discretionary decision-making by the immediate service providers.

Approach of the public management

New public management is a theoretical model related to the basic ethical principles of public access and accountability. In the developed democracies, gradual development of a quality administration prevailed. Having this as a starting point, this paper is analyzing new public management implementation and performance in the Republic of Macedonia as well as if the public administration reform meets its goals and principles.

Dait Valdo is a brilliant thinker on the “new public administration” in the postwar period. The basic principles of “New Public Administration” are participation, decentralization and “representative bureaucracy” (Wilson, 1887):

- Participation should provide changes and “disperse of power” within the organization.
- Decentralization is expected to increase citizen’s participation in the governing process.
- “Representative bureaucracy” should provide client-oriented public administration.

The “new public management” appeared in the 80s and 90s, in response to the inadequacy of previous administration models (Hughes, 2008, p. 58). The new public management in the Anglo-American systems emerged in the 20th century. The main reason was corruption in the public administration as a phenomenon on a large scale. England is a country that was in the forefront of the revolution of the new public management. Thus, the NPM in England was introduced in 1980 with Prime Minister Margaret Thatcher. Afterward, reforms have been established with John Major and Tony Blair. For example, in a period of only ten years since 1989, the UK completely restructured its civil service as part of the initiative of more than three-quarters of its civil servants” to exercise their function in new “executive agencies” as defined by the new concept (Protherough & Pick, 2002). Subsequently, the governments of New Zealand and Australia joined the movement for the NPM. Administrative reforms and new public management were placed on the agenda of the most of the OECD countries since 1995 (Kickert, 1997; Wood, 2004).

“New public management” might be considered as a sub-area of public administration. The “new public management” emphasizes the economy, effectiveness, and efficiency in governance and the delivery of quality public services. The purposes of the “new public management” are:

- to transfer the responsibilities to the operating managers in order to create greater managing flexibility and autonomy,
- to put more emphasis on risk management,
- to focus on measuring the effects.

According to the “new public management”, government involvement does not necessarily mean the provision of bureaucratic funds by the government. According to Hughes (2008), there is a trend of reducing the government's involvement through privatization. “New public management” is not a reform of traditional public administration, but a transformation of the public sector and how it is related to the government and to the society (Andrews, 2003; Christensen & Lægreid, 2001; Common, 1998; Doig, 1997; Mongkol, 2008; Vickers & Kouzmin, 2001).

Analysis of research results

Guided by the goal of the research to evaluate the role of the “new public management”, the paper refers to the analysis of laws and by-laws as well as results from scientific research projects. The analysis is based on the results obtained from an interview conducted over various categories of administrative officials in governmental bodies in the Republic of Macedonia.

The public administration faces similar challenges in all parts of the world due to the need to introduce innovations in operations and to improve its effectiveness and efficiency. Modernization of the administration not only requires changes in its strategy and structure but also requires changes in the administrative behavior. Thus, the NPM has been supported a variety of quality management systems (ISO 9000: 2000, the excellence model, European Foundation for Quality Management model) that offer support and guide public organizations to continually examine their relationships with clients and seek better solutions for work. CAF (Common Assessment Framework which means self-assessment model) is one of those tools that are increasingly used in terms of qualitative support in organizations and for building a solid foundation for one of the qualitative systems with full involvement of employees. It was developed in 1998 by the Public Service Innovation Group, an informal working group supported by the EU's General Directorate, which aims to promote the exchange of experiences and practices, as well as cooperation in order to find new innovative ways to modernize and deliver administrative and public services.

Reforms in the public administration in the Republic of Macedonia have enabled a new way of managing within the public sector. Reforms in the public administration in the Republic of Macedonia reflected the establishment of appropriate coordination and managing bodies. The new way of managing the public sector aimed at creating a responsible, effective, efficient and respondent public administration, it was implemented in the first Law on Civil Servants of the Republic of Macedonia as an independent country from 2000 (Law for civil servant "Official Gazette of the Republic of Macedonia" No. 59/2000) that stipulated establishment of Civil Servants Agency as a coordinative body that played a significant role in giving directions in the manner of managing the public administration. Also, the commitment to establish public institutions of a private nature to which the competences of public interest will be transferred is reflected in the adoption of the Law on Institutions. (Law on Institutions "Official Gazette of the Republic of Macedonia" no. May 7, 2005). This Law contains the models of privatization of the public sector and the manner of establishment of private-public partnerships, which served as the starting point for the establishment of the new public management in the Republic of Macedonia. So far, the transfer of public authority to entities in private ownership in the Republic of Macedonia is most visible in education, in the health sector, and in the social services. The state authorities

introduced NPM by the one-stop-shop system in communication with the citizens as clients, by introducing healthcare software system, etc., that indicates the commitment of the Republic of Macedonia to establish a new way of managing the public sector in the country. Another important legal act in the field of public sector management in the Republic of Macedonia is the Regulation on the establishment of organizational units for managing human resources in the public sector as well as for strategic management in the public sector (Decree on the Principles for Internal Organization of the Bodies of the State Administration, Art.8). The CAF system in the public sector in the Republic of Macedonia was used only as an experimental model based on certain projects by the OSCE, etc. In addition, the public administration reform pointed to the need for the establishment of the Ministry of Information Society and Administration (MISA). The Civil Servants Agency was the first state body to serve as the basis for establishing the NPM, with the new Law on Administrative Officers being renamed into the Agency for Administration. The new Laws on Administrative Officers (27/2014, 199/2014) and the Law on Public Sector Employees (27 / 2014, 199 / 2014) contain provisions that point to a more efficient application of the new public management. In the laws of the Republic of Macedonia of administrative nature, there are provisions that refer to the commitment of the state bodies for the application of NPM in the public sector. The Law on Administrative Officers contains provisions relating to the assessment of administrative officials, training, mentoring and measurement of achievements. The main emphasis has been placed on efficient and responsible administration. The provisions that refer to the NPM could be also found in the Law on General Administrative Procedure of the Republic of Macedonia (No. 124/2015), that contains the basic administrative principles. The Law on Administrative Procedure contains a number of provisions on discretionary decision-making by administrative officials, which refers both to the autonomy of the administrator in charge, and, at the same time, reinforce his/her responsibility.

In order to see how the legal provisions related to the NPA works in place, the paper refers to the analysis of an interview conducted with 21 respondents - employees in the state bodies in the Republic of Macedonia. Regarding the measuring of the quality and quantity of the work of the civil servants, all the interviewees answered that they do not have sets of indicators for measuring the quantity and quality of the work of the civil servants. As an exception, at the State Statistical Office, software for analyzing the utilization of working time has been introduced, in terms of utilization of the working time vs. working costs. Using this software, each employee records how much work he/she has done during the day and how much working hours he/she has spent. The establishment of quality criteria and indicators will also affect the overall perception of the capacities of the state administration, indicating how much they are trained and able to respond to the given obligations. Regarding the position of the Civil Servants Evaluation System and the Assessment Form, all respondents consider that the Civil Service Evaluation System is unrealistic, run by incompetent and subjective assessors. According to the respondents, these circumstances are due to the fact that no self-assessment has been introduced, no one is honest about him/herself and others, all of them don't share the same quality of knowledge and skills often not aware about that fact, so self-criticism does not exist at all. According to all respondents, the position of one-sided assessment leads to subjective assessment. Respondents believe that a full change of approach and assessment model should be considered. And, finally, it is not a realistic assessment of civil servants with different titles are to be valued and evaluated with the same assessment indicators.

Document Management System is a software that provides a scan of the work performance from the highest to the lowest hierarchical level. Such systems provide a scan of the capacity of administrative officials in bringing public services to citizens. The respondents answered that they did not have a document management system. Three respondents answered that they have established a similar system, which refers only to electronic archiving, which means scanning all incoming and outgoing documents and their electronic forwarding, but in addition to the electronic ones, the paper form of document flow is still used. All respondents expect the establishment of such systems in the coming period through the E-Government Strategy initiated by the Ministry of Information Society and Administration. In the framework of this activity, the Law on E-Management (No. 13/05, 14/07 55/07, 98/08) is legally backed up by some provisions that will facilitate the work of the civil servants enabling the exchange of data between the institutions.

Conclusion

From the above presented, it could be concluded that the NPM in the Republic of Macedonia is slowly implemented, which reflects the efficiency of the public administration. Therefore, there is a necessity to establish a system of measurement of administrative operations through software that will provide real indicators based on measurable indicators. This way of working is expected to motivate employees by rewarding those who achieve greater results than their colleagues. Training should be an indispensable part of the establishment of the NPM as a serious way of improving the knowledge of the administration. Given that the reform of the public administration goes in the direction of transferring competencies from the national to the local level, the doors of the public sector services are remaining open, that gradually keep open possibility of switching public services into private hands, in particular strengthening the control over the work of public institutions that have been given the authority to perform functions on behalf of the state. Thus, the amendment of the laws should be in the direction of the establishment of a quality management system (ISO standards or CAF system), a clear control mechanism through inspection bodies that will continuously monitor these institutions performance. There is a necessity to establish a one-stop-shop system between the public service providers and the state administration bodies as well as the public administration should be independent, serving to the citizens in an effective and efficient manner.

Abstract. *Democracy as efficient and effective system of governance for people should provide sustainable institutions that enable public administration and public management to meet the needs of citizens, businesses and civil society. Thereby, the dynamics of political systems in terms of instability and uncertainty concern the political address of governments and political majority. Following a strategy-structure paradigm, political systems drive the effective functioning of public management and public administration. Following a historical path and excursus, the aim of this study is to elucidate how political discontinuity and uncertainty are sources for sustainability driving public management to face and solve problems over time. Despite the increasing attention for public leadership in complex environment, research neglected the effects of policy and organizational changes on public management behaviors. Political system in Italy has known over the years frequent government turnovers, making the government average institutional life very short. Horovitz, Hoff and Milanovic (2009) define political instability as “a basic source of variation in institutions and practices (... whose) frequency and character depend on voter preferences, political institutions, and salient events and issues” (p. 107). Political instability depending on frequent government turnovers entails both a leadership change – which is based on a change in the institutional parties that constitute a majority coalition – and an ideology change – when the new majority coalition expresses a substantially new ideology. This paper elucidates a discussion on how change in the public administration environment could create a perceived uncertainty among top-managers whose assignment will end with the collapse of the government. This uncertainty affects their competencies (i.e. the motivation to lead), in terms of efforts they exert to perform their high level administrative leadership duties, and on planning activity, in terms of the goals’ difficulty related to their projects or executive programs.*

Keywords: *organizational behavior; discontinuity; uncertainty; political instability; sustainability.*

Introduction

The permanent cycle of reforms in European and US countries, inspired by the New Public Management doctrine (Lane, 2000), has refocused the interest of both practitioners and scholars on the role of leadership in making public organizations performative and efficient (Kuipers et al., 2014).

Leadership in public sector is fundamentally alike from leadership in private sector (Allison, 1986). Public leadership is characterized by the interactions of two types of leadership – political and administrative – that seek to deliver results through others and that play key roles in directing and leading the organization toward the achievement of its goals and objectives (Van Wart, 2013).

This study aims to contribute to the literature on public sector leadership, by focusing on the administrative leadership in the Italian context. Administrative leadership takes the form of a public manager in leading, managing and guiding public government focusing on the implementation of political programs (Van Wart, 2013). In our study, we propose an organizational behavioral perspective that could provide useful analysis tools to understand the behavior of public leaders working in changeable and uncertain contexts (like the Italian one, Ongaro, Ferré, Galli & Longo, 2013).

Three premises are needed in our paper. First, the introduction in Italy of the neo-spoils system, with the administrative reform in 2002, has changed the nature of the relationship between politicians and public managers through the expansion of ministerial discretion in designating top-level managers (Mele & Ongaro, 2014). According to this reform, politicians may choose to designate at the top of bureaucracy trustable and loyal managers in order to receive more professional support for their political programs. This impacts on public managers in two ways: by increasing their decision-making powers and their salaries; at the same time public manager experiences a condition of instability, higher degree of risk and a concrete possibility of being fired if things go wrong (Cassese, 2002). Today, the law of July 2002 no. 145 and the subsequent law no. 286 (conversion of Decree Law no. 262 of October 3rd 2006) regulate the spoils system in establishing the automatic assignment term for top and mid-level managers working for public administration over 90 days from the new government settlement.

Second, political system in Italy is characterized by a “stable instability” (Bull & Newell, 1993) because of the frequent government turnovers, which make the government average institutional life very short (Mele & Ongaro, 2014). Political instability depending on frequent government turnovers entails a leadership change, which is based on a change in the institutional parties that constitute a majority coalition, and an ideology change, when the new majority coalition expresses a substantially new ideology (Mele & Ongaro, 2014).

Third, democracies as efficient and effective form of government reconciling the chain of power connecting governing bodies and governors to people and citizens should automatically provide efficient and sustainable institutions leading public administration and public management to meet needs and requests of citizens and businesses. Thereby, the dynamics and functioning of democratic systems tend to rely on efficiency and fluid dynamics of political systems in terms of instability and

uncertainty concerning the political address and orientation of governments and political majority sustaining that cabinet and dialoguing with political opposition and minorities. Following a strategy-structure paradigm, political systems tend to drive and influence the effective functioning of public management and influence the effectiveness and efficiency of public administration. Following an historical path and excursus, the aim of this study is to elucidate how sustainability of public systems relies on the relationship between discontinuity and uncertainty as critical aspects and resource to drive public management to proceed facing difficulties and solving problems over time. Despite the increasing attention for public leadership in complex environment, research neglected the effects of policy and organizational changes on public management behaviors.

Starting from these premises, we draw from the literature on change uncertainty (Milliken, 1987; Bordia et al., 2004) and we aim to analyse how the perceived environmental uncertainty among public sector top-managers can influence their motivation to lead and their goal setting. Frequent government changes may create a perceived uncertainty among top-managers whose assignment will end with the collapse of the government. This uncertainty impacts on managers' motivation to lead, in terms of efforts they exert to perform their high level administrative leadership duties (Chan & Drasgow, 2001), and on goal setting, in terms of the goals' difficulty related to their projects or executive programs (Marilyn, Gist & Mitchell, 1992). Furthermore, the sense of stress and anxiety for what will be the consequences of change and how it will change their status may affect managers' perceived self-capability to perform the functions required to effectively perform their leadership role (Chan & Drasgow, 2001; Hendricks & Payne, 2007).

Finally, despite the increasing attention for public leadership in complex environment (see an example in Van der Voet, 2014), research neglected the effects of policy and organizational changes on public management behaviors (Arellano-Gault, Demortain, Rouillard & Thoenig, 2013) despite the key role of public management in exercising leadership and in planning strategic activities. Our study counts because it deepens the knowledge on the subject by identifying how political instability and organizational change show consequences on public management leadership behaviors.

Political instability and perception of uncertainty in public sector

Political system in Italy has known over the years frequent government turnovers, making the government average institutional life very short (Mele & Ongaro, 2014).

Since the 70s, Italy holds a considerable record: according to the Cross-National Time-Series Data Archive¹, Italy represents the country with the highest number of government crises (with a high rate of majority, prime minister or key ministers' turnover) in the world (an average of 1.2 per year). In this special ranking, Italy is located over above the other countries of the world, such as Lebanon, placed at the second position and which has experienced half of Italy's government crises, as well as Turkey, placed at the third position (Banks & Wilson, 2017).

¹ An archive that contains over 200 years' worth of annual global data (Banks and Wilson, 2017).

Horowitz, Hoff and Milanovic (2009) define political instability as “a basic source of variation in institutions and practices (... whose) frequency and character depend on voter preferences, political institutions, and salient events and issues” (p.107).

In the Public Management literature, many scholars have dealt with the issues of political instability, adopting different perspectives of analysis. Hurwitz (1973), for example, investigated the longest-lived governments trying to identify the conditions that can guarantee greater stability over time with reference, for example, to a legitimate legal system, to the absence of violence or socio-cultural heterogeneity. Furthermore, literature has shown that political instability generates significant organizational changes in the public sector with negative consequences for countries' economy in terms, for example, of financial development or inflation (Aisen & Veiga, 2013), thus political stability would represent a fundamental prerequisite for a more effective management of the administrative processes (Ongaro et al., 2013). In a recent article, Brady, Paparo and Rivers (2016) highlight the existence of a negative relationship between political instability and the economic performance of a country; similarly, Meyer-Sahling and Yesilkagit (2011) have shown that high political turnover hinders an effective implementation of administrative reforms. Conversely, a part of the literature focused on the positive effects of political discontinuity, considering more opportunities of meritocracy in the selection phases (Ferejohn, 1986), of skills and professionalism (Feiock & Strema, 1998) and of corruption and cronyism (de Mesquita, 2000).

Drawing on the literature on change uncertainty (Bordia et al., 2004a; Milliken, 1987) and change management in public sector (Kuipers et al., 2014), we propose an organizational behavioral perspective in analyzing public management working in changeable and uncertain contexts, like the Italian one (Ongaro et al., 2013). There is a growing literature on uncertainty during organizational change (Bordia et al., 2004a) and most common concepts focus on how managers perceive their organizational environments, recognizing that perceptual measures of external circumstances are considered more significant than objective indicators of those conditions.

Perceived uncertainty is defined as “an individual's perceived inability to predict something accurately” (Milliken, 1987, p.136) because of the lack of information (Berger & Calabrese, 1975). Individuals operating in an environment that is perceived to be complex and rapidly changing tend to experience a higher level of uncertainty due to the difficulty in carefully predicting the impact of their actions and decisions (Daft, 2001). Uncertainty is “one of the most commonly reported psychological states in the context of organizational change” (Bordia et al., 2004a, p.509) and this perception refers to internal and external factors to the organizations (Beckman, Haunschild & Phillips, 2004): internal factors are, for example, the ambiguity of roles and the lack of control and they refer to the organizational structure and the decisional processes (Bordia et al., 2004a); external factors instead refer to the dynamic, unstable, complex and heterogeneous environmental context for which the resulting effects for the organizations are less predictable but equally important.

Some scholars (e.g. McCabe, 1990) hypothesized that uncertainty is based on two dimensions, namely *complexity* and *stability*, while others (Boynton, Gales & Blackburn, 1993) focused on the *availability of needed information* and on the *predictability of future outcomes*. A relevant contribution in the literature on perceived uncertainty is provided by Milliken (1987), who identified three dimensions of perceived uncertainty and

different types of coping response associated to each dimension: *state uncertainty*, *effect uncertainty* and *response uncertainty*. *State uncertainty* concerns the perceiving that the organizational environment is unpredictable and this generates uncertainty among managers about the probability or the nature of changes in the environment. The second dimension, *effect uncertainty*, refers to the implications of a given change and, hence, the ability of individuals to predict the impact of environmental changes on their organization. Finally, *response uncertainty* refers to the potentially unlimited number of options and consequences associated to a given choice, so it is difficult to predict the cause–effect relationships for each decision in a context of change.

Literature on perceived uncertainty highlights significant relationships with behavioural variables. Perceived uncertainty is positively associated with stress (Schweiger & Denisi, 1991) and turnover intentions (Johnson, Bernhagen, Miller & Allen, 1996) and it is negatively associated with job satisfaction (Rafferty & Griffin, 2006), psychological wellbeing (Bordia et al., 2004) and trust in the organization (Schweiger & Denisi, 1991). Nevertheless, many of these studies analyse the impact of uncertainty on workers' behavior without considering top management positions (Arellano–Gault et al., 2013). Furthermore, in spite the long history of research on managerial perceptions of changing environments, there has been scant systematic investigation in the public sector (Andrews, 2008), where other conceptualizations and taxonomies on uncertainty are proposed.

A contribution in the literature on perceived uncertainty in the public sector is based on the study of Bordia et al. (2004a), who introduced the distinction between *strategic*, *structural* and *job-related* uncertainty in public administration. *Strategic uncertainty* refers to uncertainty regarding organization–level issues, such as the reasons for change, the future direction of the organization or its sustainability. For example, a public manager experiences strategic uncertainty when, in a context of changing government and policies (e.g., privatization, funding cuts), he experiences a lack of clear vision and this will provide uncertainty regarding the impact of change on administration's strategic direction. *Structural uncertainty* refers to changes in the administration's internal organizational structure. An example is the merging of two different offices that is likely to produce changes into internal hierarchies: this type of change generates uncertainty about the chain of command and the responsibilities of employees within the public offices. Finally, *job-related uncertainty* refers to job security, career opportunities, and changes in the role and tasks to be performed; an example is the introduction of new technologies or the downsizing of certain programs and activities.

In the Public Management literature, some studies have shown that political uncertainty and discontinuity have consequences on economic growth (Aisen & Veiga, 2013) or on financial development (Campos, Karanasos & Tan, 2012), while very few studies focus on how political instability influences public sector reforms and organizational changes. In this regard, studies on the implementation of reforms in the public sector hypothesize the importance of a relationship between politics and administrators, recognizing a role, for the former, in addressing/determining (and not just controlling) the behaviors of the second. These studies hypothesize a far more collaborative relationship between politics and administrators, which is alternative to the classic dichotomous model (Dunn & Legge, 2002), but they do not consider the effects that the political instability could have on the effectiveness of this relationship between the parties.

In wider terms, despite public administrations often challenge organizational changes associated to a great deal of uncertainty among employees (top managers included), there are still very few studies dealing with the determinants and consequences of this uncertainty on the performance of the public management. For example, Jung and Ritz (2014) have dealt with the effects of public reforms explaining that frequent reforms in public administrations generate the perception of instability among public employees, who are likely to experience a reduction in affective organizational commitment; in a study on the effects of the administrative reform in Korea, Song (2008) examined different kinds and dimensions of organizational uncertainty – structural and systematic, new administrative demand, job-related, and unpredictability in the decision-making process – and their interrelation in the case of a paradigm shift in the public sector.

The Italian setting

Italy over the years has been characterized by a “stable instability” (Bull & Newell, 1993) that fuelled a fiery debate on the inefficiency of public administration (Cerase, 1990).

Since 1946, that is the year of the first government of the Italian Republic, in Italy 64 governments followed with an average duration of 1.1 year and this statistic shows how this frantic succession has made Italian government power unstable. Compared to other countries, such as Germany², Italian political fragmentation makes very difficult to imagine a long-term political planning (Furlong, 1991). Another example is France, where the average duration of the 39 governments of the Fifth Republic (from 1958 to today) has been of 1.5 years.

The Italian governments of the last 20 years have been carried on by minimum winning coalitions “just as large as [their participants] believe will be winning and no larger” (Riker, 1962, pp.32–33). In fact, centre-right parties and centre-left parties have alternated, together with a small centre opposition representative, and this has generated negative consequences in reforms’ implementation and in administrations’ strategic planning.

Without doubt, the chronic political instability in Italy has generated continuous interruptions in the planning and in the implementation of government policies (Cassese, 2012) that have hindered all the initiative aimed at innovating the administrative machine. One of the causes must be identified in the short-term orientation that politicians and administrators have held over the years, focusing on objectives that were to be achieved before the transition to a subsequent government. This has obviously generated repercussions on reforms’ front, since many of those have been approved and implemented with difficulty, as well as the continuous turnover of the political leadership also due to the climate of mistrust and dissent against majority coalitions which, for the short duration governments, have never had time and opportunity to legitimize themselves in the eyes of public opinion.

Political instability, as well as affecting the stability of strategic reform strategies, also shows direct impacts on the stability of the roles of public managers. With the

² Since 1949, the foundation year of the Federal Republic of Germany, 29 governments followed with a government’ average duration of 2.9 years.

establishment in Italy of the majority electoral systems, it has been introduced in Italy the mechanism of the neo-spoils system, introducing the principle according to which politicians may choose to designate at the top of bureaucracy trustable and loyal managers in order to receive more professional and moral support for their political programs. The spoils system in Italy is governed by the Law of 15th July 2002 No. 145 and by the subsequent Law of 24th November 2006 No. 286 (conversion of Decree Law No. 262 of 3rd October 2006) and the ratio is in the need for trust and harmony between administration and politics as a necessary element for the good performance of public administrations. The common purpose, guaranteed by the fiduciary nature of the appointments, determines a greater cohesion and action synergy between politicians and managers. This impacts on public managers who experience a condition of greater uncertainty as they are pressed by two opposing needs: on one side, they have the task of translating the political address into measures and management actions and, at the same time, they are required to guarantee the impartiality of the administrative action (Cassese, 2002).

A behavioral perspective

Managers tend to experience organizational change differently compared to other categories of workers (Karp & Helgø, 2008), since they are often more directly involved in the decision-making processes and, in the case of public managers, they are aware of the decision-making guidelines of politicians. The perception of uncertainty, therefore, tends to be lower, as managers often act as an “active” part of the change process. However, sometimes political dynamics become very frenetic and almost irrational, up to the point that the reasons for change are not clear even to top managers, who experience a sense of uncertainty and instability with relevant consequences for their work. In these circumstances, public managers may experience a low level of organizational identification (Dutton, Dukerich & Harquail, 1994): since individuals act based on their sense of belonging to different social groups, it is likely that frequent governments’ changes do not allow a coincidence between the political values of managers and the values of the politicians.

Organizational identification provides for recognition of one’s own values in those of the organization and it can help to understand why some individuals commit themselves to carry out their activities more self-denial than others (Dukerich, Golden & Shortell, 2002). Managers who experience “temporary identities” (Ibarra, 1999) or an ambiguous organizational membership – as may be the case of Italian political and administrative system, continually “provisional” and unstable – are in fact less identified with the organization and, consequently, less motivated to carry out their tasks.

Probably, this uncertainty will determine a decrease in motivation to lead for public management (Weick & Sutcliffe, 2011). Motivation to lead (MTL) refers to the tendency to seek out leadership positions and to the effort managers exert in performing their leadership duties at a high level; it is a three-dimensional construct based on affective, social normative and non-calculative identities (Chan & Drasgow, 2001). MTL affects the individual’s participation in leadership roles and activities due to self-inclination and preference, perception of and conformation to social norms, and lack of calculativeness (non-calculative MTL) (Hong, Catano & Liao, 2011). Public top managers therefore may show a high level of dissatisfaction at work because they do not perceive the satisfaction and the pleasure deriving from being leaders, they are not

motivated to lead by social and normative reasons, such as a feeling of commitment to the group, and finally they are not encouraged to sacrifice themselves for uncertain and fickle objectives, as the MTL definition (Amit, Lisak, Popper & Gal, 2007).

Another important point is that, in a condition of high political turnover, managers may find it difficult to plan and set medium and long-term goals. Drawing on the goal setting theory (Latham & Locke, 1991), individuals' performance is the result of their will, so that an individual who has a clear idea of what he wants to do will have a better performance than those who have unclear goals and ideas. Some managers may feel disoriented in carrying out their duties: as governments alternate in a frenetic way, managers fail to plan long-term goals because there would be no possibility of reaching them. Since the context is perceived as insecure and unreliable, it certainly influences and affects employees' propensity to reach goals (Borgogni, Dello Russo, Petitta & Latham, 2009), since individuals want to grasp the relation between what they do and the desired outcome (Bandura, 1997).

Conclusions

In conclusion, starting from the consideration that the setting of uncertainty negatively affects self-regulatory mechanisms and performance (Arenas, Tabernero & Briones, 2006), it should be useful to verify if and how uncertainty impacts on professional identification, in terms of recognizing the own personal values in those of the administration, on MTL, in terms of efforts in performing high level administrative leadership duties, and on planning activity, in terms of the setting goals' difficulty. Strategic, structural and job-related uncertainty experienced by public managers in Italy could be the cause for the general inertia of the public sector (Cristofoli, Nasi, Turrini & Valotti, 2011).

Abstract. *The Learning Organization is the organization that continuously learns and readapts. It is the place where employees constantly develop the capacity of generating the results they truly target, where new and bold thinking methods are encouraged, where collective aspirations are released and where people continuously discover how to learn together (Senge, 1990). This concept emerged in the corporations of the 1980s, but in the meantime it also became attractive for the public sector. This paper analyses the extent to which the concept of 'Learning Organization' exists in the public sector in Romania, the current learning capacity of the organizations in this sector and the impact of the concept at organizational level. As research instrument, the questionnaire designed by Bruce Britton (1998) 'The Learning NGO' was applied within six public organizations. The research questions addressed in this paper are: (1) What is the degree of use of the learning concept to support and facilitate the development of employees, organization itself, institutions and local community?; (2) What is the impact of the learning concept on the public organizations?*

Keywords: *learning organization; public sector; local public organizations; central public organization; Romania.*

Introduction

Public organizations in Romania have the desire to continuously improve and adapt to various internal and external challenges. Unfortunately, not all of them succeed. There is a low rate of services delivery and organizational improvement, especially in the public sector. A continuous improvement process is highly linked to a commitment to learning, but it seems that not all managers understood this reality. Problem solving, placing a public good or service, but also changing or innovating a process in public sector, need to be addressed immediately by a new approach.

In the absence of learning, the organizations – and the employees – simply repeat the old practices. Related to private organizations, the concept "learning organizations" has been mentioned for the first time in the late '80s. Managers from private sector have

recognized the link between learning and continuous improvement and have begun to refocus their companies around it. Scholars have jumped too on the bandwagon, beating the drum for “learning organizations” and “knowledge-creating companies” (Garvin, 1993, p. 78). The concept “learning organization” has spread towards the other sectors.

Theoretical background

Learning organization. Definitions, characteristics and functions

Definition of learning organization

Chetley and Vincent (2003) defined the development of a learning organization as an ongoing, systematic process requiring trust and a recognition of the subtlety and complexity of human relations and describe three stages in this process; firstly, individuals and teams are encouraged and supported to learn; secondly, these processes are socialized or institutionalized; and thirdly, learning is at the heart of an organization, meaning that learning is used to transform and develop the organization (Al-Nsour & Al-Weshah, 2011, p.14).

There are many definitions of the learning organization (see Table 1).

Table 1. Learning organizations definitions (The authors based on literature)

Authors	Definitions of learning organization
Senge, 1990	Learning organizations are places where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together.
Pedler et al., 1991	A learning organization is an organization that facilitates the learning of all of its members and continuously transforms itself in order to meet its strategic goals.
Garvin, 1993	A learning organization is an organization skilled at creating, acquiring, and transferring knowledge, and at modifying its behavior to reflect new knowledge and insights.
Marquardt, 1996	Learning organizations are companies that are continually transforming themselves to better manage knowledge, utilize technology, empower people, and expand learning to better adapt and succeed in the changing environment.
Marsick & Watkin, 1999	An organization that emphasizes three keys: system-level, continuous learning; created in order to create and manage knowledge outcomes; which lead to improvement in the organization's performance, and ultimately its value
Griego et al., 2000	An organization that constantly improves results based on increased performance made possible because it is growing more adroit.
Templeton et al., 2002	An organization in which employees are continually acquiring and sharing new knowledge and are willing to apply that knowledge in making decisions or performing their work
Armstrong & Foley, 2003	A learning organization has cultural facets (visions, values, assumptions and behaviors) that support a learning environment; processes that foster people's learning and development by identifying their learning needs and facilitating learning; and structural facets that enable learning activities to be supported and implemented in the workplace.

Table 1 illustrates the fact that there is no unique comprehensive definition of learning organization.

A learning organization may be described as an environment where organizational learning is structured so that teamwork, collaboration, creativity, and knowledge processes have a collective meaning and are valued (Confessore, 1997, p.5). It is important to mention that learning organizations are more than simply 'containers' for individuals who are learning, one indicator of a learning organization is that everyone, irrespective of their position, makes a valued contribution to the organization's learning (Britton, 1998, p.4). The concept of organizational learning itself requires an understanding of three important terms (Britton, 1998, p. 4):

- Information - is the simple fragmented raw material of facts, opinions and ideas of which knowledge is made;
- Knowledge - systematically organized information which, by the processes of analysis, comparison, testing and generalizing can be used to answer complex questions;
- Wisdom - this involves uniting the facts and insights of knowledge with the fruits of experience in a way which can usefully guide action.

Characteristics of learning organization

The literature has shown various characteristics of learning organization, but the authors of this paper consider that Pedler et al. (1991) have presented more comprehensive characteristics (Britton, 1998, p.2):

- A learning approach to strategy (encouraging flexibility by including strategic learning feedback loops);
- Participative policy making;
- Informing (using information technology to inform and empower people);
- Formative accounting and control (structuring financial systems to assist learning);
- Internal exchange (ensuring constructive, supportive relationships within the organization);
- Reward flexibility (using creativity in how people are rewarded for good performance);
- Enabling structures (avoiding multi-level hierarchies and encouraging flattened, collegiate-style structures);
- Boundary workers as environmental scanners (acknowledging the value of those who deal with the 'outside world' as sources of crucial information which can inform decision-making);
- Inter-organizational learning (identifying opportunities for networking, strategic partnerships, benchmarking and joint learning activities);
- Learning climate (facilitating experimentation and allowing mistakes providing they are used as learning opportunities);
- Self-development for all (resources and encouragement for self-development are made available for all members of the organization).

The nature of a learning organization becomes easily perceptible when compared with a traditional one. The differences between these two are presented in Table 2.

Table 2. Typical characteristics of traditional and learning organizations
(Skuncikiene, Balvociute & Balciunas, 2009, p.65)

Characteristics	Traditional organization	Learning organization
General values	Utility	Excellence and mastery Organizational renewal
Style of management	Control	Assistance Training
Strategy. Action plan	Top-down approach Road map	Everyone is consulted Learning plan
Structure	Hierarchy	Flat structure Dynamic networks
Characteristics of personal	People who know (experts) Knowledge is power	People who learn Mistakes are tolerated as inseparable part of learning
Exceptional skills of personnel	Applicable learning	Generative learning
Evaluation system	Financial performance measures	Financial and non-financial performance measures
Teams	Work groups in separate functional departments	Cross-functional teams

The structure of learning organizations illustrates that learning is a prominent feature at a number of different levels (Britton, 1998, p.3):

- individual learning;
- team or work group learning (sharing lessons between individuals working together);
- cross-functional learning (sharing lessons between departments and sections);
- operational organizational learning (focused on improving practice, increasing effectiveness and efficiency);
- strategic organizational learning (learning to deal with significant changes in the environment which affect the overall strategy of the organization).

Functions of a learning organization

Efficient learning implies the application of specific key-functions, in all (public, NGOs and private) organizations. These functions are (Britton, 2002, pp.14-29; Britton, 1998, pp.12-20) (see Figure 1):

- *Creating a learning culture.* A learning culture is an organizational environment which enables, encourages, values, rewards and uses the learning of its members both individually and collectively;
- *Gathering internal experience.* The organizations have two main knowledge sources: the internal experience and the lessons learned from other organizations. The learning organization exploits the internal experience and transforms it into practical and accessible lessons, especially not to repeat mistakes and to reappraise its success;
- *Accessing external learning.* The learning process within the learning organizations is based also on the lessons learned from other organizations. The learning organization is open towards partnerships, NGOs or public and private organizations to learn from their experiences, failures and success;

- *Communication systems.* The communication systems, both formal and informal, are very important as they offer the learning support for information communication, and these have to be developed.
- *Mechanisms for drawing conclusions.* Drawing conclusions is a process which needs to be seen as the responsibility of the whole organization and should, ideally, happen as near to the source of the experience as possible;
- *Developing an organizational memory.* A learning organization needs mechanisms which enable an individual's memory to be 'down-loaded' into a knowledge management system so that everyone can continue to access that person's knowledge long after the individual may have moved on from the organization;
- *Integrating learning into strategy and policy.* One way of building lessons learned into the fabric of an organization is to develop strategies and policies which embody the lessons it has learned. This provides the organization with a framework for decision-making and resource allocation which is grounded in the organization's own experience and what it has learned from other organizations;
- *Applying the learning.* The ultimate test of learning is the ability to apply what has been learned. Only when learning is applied in the work setting can we say that a continuous learning cycle has been created.

Figure 1. The eight key functions of a learning organization
(Britton, 2005, p.41)

All these functions are interconnected. Creating a supportive culture embraces the other seven because without a supportive organizational culture of learning, there is unlikely to be commitment to the other functions (Britton, 2005, p.41).

Learning organization in the public sector

Christiensen et al. (2007, p.4) considers that the main argument in supporting the conception that public and private organizations are fundamentally different in key aspects is the fact that public interests differ from private interests, since the public sector must consider a broader set of norms and values. Many considerations must be weighed against each other, and democratic considerations, constitutional values and public welfare are given much more weight in public organizations than in private organizations. Second, the leaders of public organizations are accountable to citizens and voters rather than to special groups. Third, public organizations require a greater emphasis on openness, transparency, equal treatment, impartiality and predictability.

The need for change comes usually from the external environment, especially in public organizations. The pressure for change is constant, and the response often triggers a more profound pressure for change. The primary objectives face the resistance of external factors, and thus new objectives are set; innovations created to solve a certain problem often lead to new problems (Blau & Scott, 1962, p.250).

The real and actual functioning conditions of public organizations determine the creation of behaviors oriented towards the organizational learning culture development, such as creativity, commitment, responsibility, openness towards changes and continuous learning. This is the condition to accomplish efficient innovative operations and to implement an efficient innovation.

The change has to come from the inside of the organization. In his theory-driven article, which scrutinizes the chaos and transformation theories in historical and complementary standpoints and analyzes their contributions social science and public management, Farazmand (2003, p.362 apud Maden, p.79) states that "organizations that learn, adjust, and adapt to external pressures causing systems breakdown and bifurcations can survive and evolve, and their evolution comes through internal learning and transformation". Therefore, public organizations should not only strive to keep up with the rapid change in environmental conditions but they should also learn something from change process and combine it with their own structure. In other words, public organizations should gradually transform themselves into learning organizations which are characterized by constant organization learning, flexibility and an adaptive stance (Maden, 2011, p.79).

Methodology

Research design. In order to achieve the objectives of this paper and to respond to the research questions, the questionnaire elaborated by Bruce Britton (1998) in his book 'The Learning NGO' has been applied to public organizations.

Defining the sample. The questionnaire has been applied in six public organizations, from both central (three organizations) and local (three organizations) from Bucharest and other cities. Twelve questionnaires were applied in Ministry of Health (departmental level), eight questionnaires were applied in Ministry of National Education (departmental level), eight questionnaires were applied in Prefecture of Bucharest (departmental level), twelve questionnaires were applied in Cosoba City Hall (commune located in Giurgiu county), thirteen questionnaires were applied in Târgoviște City Hall

(county seat of Dâmbovița county) and eight questionnaires were applied in Cornu City Hall (commune located in Prahova county). The respondents completed the questionnaire anonymously.

Data collection. The questionnaire is composed of 40 questions with the aim to identify the "learning profile" of the six public organizations in Romania, structured in the eight key functions presented below (see Tables 4 - 9).

Table 3 presents the correspondence between the functions and the number of question.

**Table 3. The correspondence function - no. of question
(the authors based on questionnaire)**

Function	No. of question in the questionnaire
Creating a Supportive Culture	1, 16, 17, 32, 33
Gathering Internal Experience	2, 15, 18, 31, 34
Accessing External Learning	3, 14, 19, 30, 35
Communication Systems	4, 13, 20, 29, 36
Mechanisms for drawing conclusions	5, 12, 21, 28, 37
Developing an organizational memory	6, 11, 22, 27, 38
Integrating Learning into strategy and policy	7, 10, 23, 26, 39
Applying the Learning	8, 9, 24, 25, 40

A plot organizational profile has been created through the questionnaire, which gives the 'learning profile' of the organization (see Figures 2 - 6). In regards to the eight applicable functions for learning organizations, the profile shows where the organizations strengths and weaknesses lie. Before distributing the questionnaire, the authors have verified the applicability of questions' wording within the organizations. The questionnaire has been adapted for the public sector, the size and the structure of the organization/department, without affecting the relevance for the organizational learning function. Also, the questionnaire identifies the respondent's job/position, sex and years of experience within the organization. The minimum requirement to complete the questionnaire was that the respondent must have worked for at least one year within the organization. The respondents were from both managerial and executive levels, both public servants and temporary staff.

The data collection was made online between January 20 - March 20, 2018 and all questionnaires have been validated.

Results

Analysis of the findings are presented below.

Figure 6. Cornu City Hall Learning Profile

The results illustrate the fact that the central public administration organizations cannot be considered learning organizations, compared to the local public administration organizations, where some functions can be identified (for example Târgoviște City Hall).

The awareness to apply the “learning organization” concept within the public sector is linked to the implementation of changes, innovations and reforms with the final aim to satisfy the needs of citizens.

The managers and employees of public organizations have to engage into the efforts of implementing the elements of learning organizations. On the contrary, the organization can find itself in the situation to no longer deliver the public service in accordance with the citizens’ needs, without the possibility to reinvent or to adapt to the current challenges. Also, they have to constantly develop new knowledge management abilities through a continuous learning process, to develop a learning culture, to manage the changes with a positive attitude and to have a clear vision of what it has to be achieved.

It is important that the employees agree with the managers on the learning organization strategy. In this manner, public sector organization could become learning organizations.

There are external and internal barriers in the transformation of public organizations into learning organizations as well:

- External barriers: low budget that sometimes does not allow business continuity, changing legislation quite often does not allow institutional development, involving politics in the organization's activities may lead to inconsistency of organizational objectives (especially the fact that political representatives are changed very often).
- Internal barriers: political management, bureaucracy (focusing on the system and respecting procedures), powerful hierarchical structures, authoritarian management, strict hierarchical control, monopoly in delivering the services and goods, reticence to train the employees, the personnel's resistance to change due to insecurity and fear of taking risks, lack of communication with managers, underdeveloped communication systems, all these obstruct the public organizations to become learning organizations.

Conclusions

The research has revealed good practices examples of learning organizations in public sector. Generally, one can observe a low degree of using the concept for supporting and facilitating the development of employees, organizational process, institutions and local communities.

The impact of learning concept on the public organizations, if these would change into learning organizations, could mean: increased adaptability – the organization could face more easily the challenges and unpredictability; increased efficiency and efficacy – the organization could make better use of its resources; increased personnel motivation – the employees could feel more valued and more influent; capacity to keep highly trained employees and their knowledge – better systems to reward the employees' contribution to the organizational development; increased capacity to initiate change – learning offers confidence and the necessary information to initiate projects and to take risks.

Learning organizations accomplish their mission through activities such as: systematic problem solving, practicing, learning from own experience, learning from the experience and good practices of other organizations, but also through accelerated information transfer within the organization.

Various public organizations from Romania develop these activities more or less, but not all of them succeed in changing into learning organization. This is mostly based on some rare situations and examples, not on the systems and processes to support these activities and to integrate them into a daily operational structure.

Abstract: Identification, evaluation, analysis, and diagnosis of the financial risk management issues in a public organization is a troublesome step and at the same time a complex approach of the management process. The state-owned companies' organization structure has had various forms and levels of management and at the same time the specific administrative knowledge. For various reasons, objective or subjective, some managers being nominated in positions of management or execution caused a multitude of financial risks. From simple opportunity or threats to financial risk, there are many theoretical arguments through which the management in the public organization in our country can be explained, by always discovering specters of approach, complacent to one study or another. The article's goal is to underline the role of making a study of impact based on solutions given by theoretic concepts and terms from financial risk management field. We conceive this case study by using a comparison between an existing company and a former company, bankrupted, sale and ultimately closed, by applying to each of them the contemporary financial and business realities of Romania. In order to draw valuable conclusions in the field of financial risk management, the researchers underline some differences between our two examples chosen from the car industry. Likewise, we would like to present the manner in which a good style of managing of financial risk in an organization has transformed Dacia-Renault cars factory into one of the best-performing companies in Romania. The study aims to analyze the risks of the two major Romanian plants, what measures could be taken in the short, medium and long-term to minimize and/or limit their effects and to prevent bankruptcy, as unfortunately, did not happen with ARO. The applied methodology is that of analysis based on case studies, being a quantitative analysis. The research paper presents the results of this comparative case studies analysis, which attempts to highlight the main aspects of the ways in which the threats and risks were mitigated and depending on their relevance, the findings were transformed into graphs which will make it easier for readers to understand the research results. Then a synthesis of the conclusions and the results obtained from the research will be presented.

Keywords: financial risk; financial management; budget; financial plan; risk analysis.

Introduction

The automobile industry in Romania has had experienced a dramatic change in the cars' industry during the 20th century as the result of the introduction of automotive engineering technology in each country around the world. The comparative financial analysis suggests that adopting innovation in a changing industry is not a new phenomenon, and how companies can manage and make use of financial risk management. Moreover, the example of how the human resource could influence more than technology that leads to changes in this sector was almost inevitable, especially in ARO case. Case studies analyzed in the back to back system reveal that although both have benefited from the same market conditions, the same political conditions, both have been affected by the same factors, each of them has gone on another path. The dramatic changes affected different parts of the companies in different ways. If a company sees itself as a resilient company oriented to the future, the image itself could have been affected by the changes for short-term but it changed and adapted its every resource, human and material to rebuild the factory. The study results from the factors that underlie a change in the industry. Then we studied the phenomenon at the industrial level, and then see how a company in the car industry is affected by reacting and changing business environment. Finally, the change of industry was reconsidered at the organizational level. The paper shows how a successful automobile factory could be affected by the consolidation of democracy in our country, how was changed the industry above all the implications. The purpose of this article was rather to study how a company is reacting to, or possibly drives, a change of industry and the strategic considerations that are associated with it.

Theoretical framework based on literature review

In this section, we explain all the appropriate theory that is used in the literature to analyze empirical data collected from the public information about ARO and Dacia. We define the important concepts for using them in the case study, the criteria that have affected the Romanian automotive industry in more than 30 years and what it takes to a company to be able to deal with the new problems that occurred in the post-communist era. The characteristics of the organizations in a crisis of identity are reflected in financial situation (the balance sheet, assets, profitability or cash flow) and financial risks (credits, residual value, foreign exchange, commodity prices, energy prices, interest rates). In Romania, in the communist ages, the financial risk or the management risk was almost non-existent for the industry, capital markets, or life in general. As such, the risk was more associated with socio-human sciences. In the XXth century, "the risk has been associated with the natural sciences, not with the financial and insurance theories, in the 2000's the concept of risk gained importance among the decision-factors in the business world. The crisis, starting with the second half of 2008, covered almost the entire planet, due to the contamination effect." (Treapăt, 2011, pp.9-13). Although not aware, it seemed that the high management from the automobile industry was at risk "in danger of loss" (Murphy, 2008, p.39). They did not understand that the unique way to survive in the international field of cars market was to adapt all the factories and to learn faster if possible to protect against malevolent acts against their organizations. It was impetuous necessary to develop a security risk assessment and management process. It seemed that they did not know "how to perform a complete risk assessment that assists the project owner and manager in deciding why to either accept the calculated risk or reduce the risk to a more acceptable level" (Biringer,

Matalucci & O'Connor, 2007, p.XXI). The risk management is usually taken into consideration in nowadays life in the hard times of a crisis or after the balances are noted with losses. "The losses emphasize that the systems were inadequate so that the risky positions being taken were simply not known. It is also important for the managers to continually think outside the box about what could go wrong so that as many potential adverse events as possible are identified" (Hull, 2015, p.673). Then, in the 90's, the Romanian industry had been faced with problems linked to the capitalist competitive market in all possible directions. In those years, "the perception of an increased risk, the lack of trust and the fear of exposing themselves to dangerous situations or malicious strangers seem to be the most important barriers" appearing in every business, regardless the age, sex or experience (Vătămănescu & Pînzaru, 2018, p.10).

Considering the above, it can be said that the risks to which the Romanian factories were subjected had to be quickly transformed into opportunities but not all managers knew or wanted it. It should be taken into account that the limits of risk assumption could be a lesson learned from the losses. "Ideally, overall risk limits should be set at board level and be converted to limits applicable to the individuals responsible for managing particular risks" (Hull, 2015, pp.644-645). Management risk requires a comprehensive and interdisciplinary approach to deal with the external and domestic threats. A lot of mistakes should be avoiding, like focusing on narrow and most popular measures and using poor communicating among workers and managers, assuming that the risk management must always be expensive and complicated as founded Wereda et al. (2016, pp.88-89). The necessary steps to avoid mistakes would be connected to the following tryptic: business performance, value protection, and value creation. (E&Y Industries Insights, pp.2-6).

The methodology of research

The research method used in this paper is based on case study because it is the most appropriate method when we want a thorough and in-depth investigation of a phenomenon, which consists of analyzing the financial risk of two state companies, one successful, and one bankrupt. The more appropriate the research method is to counter face-to-face with two case studies, as we look at the different ways in which two companies evolved over time, where risk management was completely different. In the current study, we face two very different cases from the point of view of financial risk management, but very similar to the organizational form, because both companies were established by the state, so they were at the beginning public companies. They have worked for many years in the centralized economy, but their fate was different from the privatization methods applied to each. Any other research method would have been chosen, it would not have been able to cover all aspects of reality as analysis based on case studies. The reader will identify a qualitative research, whose conclusions will be capitalized on comparing important indicators expressed by graphic methods, letting them be easier to understand. Flyvbjerg (2011, pp.301-316) identifies that the most important is how you choose your study unit (in our case the two companies), which must lead to intensive research, rich in detail, complete and not neglect the reality of the company studied with the external environment. The advantages researcher considered when chose the case study as the research tool were that the case study uses as subsequent research tools, as document analysis, participative and nonpartisan analysis, opinion poll and the reality-proven experiment. In the case of our research, we decided to use as much as possible the tool

that Yin (2008, pp.79-85) presents in his paper "Case Study Research: Design and Method", namely the exploratory, descriptive and explanatory case study. In this situation, field research, collecting data from various sources, can be made before defining research assumptions. Finally, in capitalizing the conclusions we will identify the cause-effect elements and explain the causal links that were identified in our study. Multiple case studies give us much more convincing conclusions because we have the benefit of comparing cases in addition to individual conclusions. Based on the methodological basis described earlier, this section presents the empirical data we have gained from our case study companies.

In the current case study, we have two examples as a research base. One example is Dacia, being a good example of adapting the factory to the new capitalist environment. The other one is ARO, nowadays, the car factory is closed for many years. This happens even that ARO was in the 70's and 80's more successful than Dacia. The fact that both car factories were selling many export cars creates a good and equal starting point for our study. How each of the subjects analyzed after the state privatization evolved depending on the financial risk management measures applied by the new shareholders in each case.

The analyzing criteria for two kinds of organizations are highlighted in our case study. To make the case study possible to compare the two factories, the paper takes into consideration the old corporate governance rules for ARO. The board of directors was not organized for efficiency and effectiveness for the free market. The company was viewed as a strong hierarchy, with centralized imposed hierarchical decision rights and structure. Their administrative structure was not based on business function with functional leaders and global functional management groups. During the communist ages, the corporate culture was ruled by fear of failure and perception of others decision makers from the center. To the contrary, the situation at Dacia is different from that at ARO. They are part of Renault holding, organized for learning innovation and customer impact. This company focuses on process to build capabilities and stronger ecosystem (Wereda et al., 2016, pp. 22-23). The company is viewed as an agile network. Collaboration and knowledge sharing fuel the team leaders. The structure is based on work and projects, with teams focused on products, customers, and services. The old and new rules made the difference between the nowadays Dacia - Renault and the bankrupted ARO. In the crisis times, the organizations that develop their businesses are resilient organizations because adapting the risks and threats and transforming in an opportunity is an organization that looks to the future, it is not stuck in time. Based on our research, we found that one of the most important factors for transformation of Dacia in a successful international brand were the leadership in the company, the inter-institutional communication and the implementation of the risk management system.

The main research hypothesis that we propose is that the success of a company (be it state or private) grows directly proportional to the quality of financial management of the company's assets. A very good financial risk management can make a difference between success and bankruptcy.

Beyond the description of the methodology used and the reasons why we consider this research tool to be the most appropriate to the surveyed situation, it remains to establish as the main objective of this research the identification of some lessons that company's managers must learn from now on. The actions taken in the case of Dacia

must be emphasized and remembered because they have led to the mitigation of risks and the mistakes made by inappropriate actions or even by inaction in the case of ARO.

Research results

ARO Case Study

We used as sources of information to carry out the research, first, the accounting statements of the two companies, ARO and Dacia, filed with the Ministry of Finance and which are public information. These financial and accounting studies have been analyzed, processed and restructured in order to be better understood, to highlight some indicators more clearly. What follows is a capitalization of research, a synthesis of how the two companies have evolved.

In 1957, the ARO production started with a model called IMS-57 (IMS-State Metallurgical Enterprise), but the production was stopped in 1975, after 80,000 assembled copies, according to Dnistran (2015, pp.1-3). Until the early 1980s, ARO was a world success, ranked fourth in the world after the number of field cars sold and outlets (after Jeep, Land Rover and Toyota), the end of the decade brought a moment of the epiphany: ARO factory had to be upgraded if export competitiveness was to be maintained.

We chose to analyze the ARO's registered indicators during the most sensitive period of the factory, 2000-2004, years in which ARO was sold by the state in a questionable way to a phantom company that did not continue the company's successful business, but sold the piece of the company's assets and fired the employees. The huge volume of debts exceeds the value of current assets in the years 2000 – 2004. Between 2001 and 2003, the current debts exceeded the total assets. In this period, the company's own capital registered negative values, as can be seen in the following figure. The situation at ARO, during these years, was bad. It was no possibility to pay the debts to third parties, both during the course of its activity and its liquidation.

Because of poor indicators, as can be seen in Fig. 1 above, ARO is no longer receiving loans from banks, but other tick-borrowers borrow on its behalf and buy cars at lower prices than those dictated by the market, which they then sell up to four times more expensive. The debts of the company were growing exponentially year by year, reaching a peak in 2003.

Figure 1. ARO Main Indicators Evolution

At the end of 2004, corporal assets have a downward trend due to their alienation, as well as to the disposal of fixed assets. The shares held by ARO in other companies represented the financial assets of the company. The receivables of the company and the cash reserves of the company reach a minimum of - 682,232 thousand lei. The equity of the company recorded annual negative values. Year1995 was the last year with a significant profit. Until 2004, the company recorded losses at an exponential rate.

Figure 2. ARO-Evolution of Equity

At the end of 2003, the debts of the company are growing from year by year, reaching the pick, 194,361 thousand RON. The huge volume of debts made it exceed the total value of the net current assets in the years 2000 - 2004, more in the years 2001-2003 the current debts exceed the total assets. The total cumulative loss between 1997 and 2004 was 207,684 thousand RON. From the above figure, it is clear that ARO has a big problem with the sources of financing, the value of Equity being negative.

Figure 3. ARO-Evolution of Losses

From Figure 3 above we can understand how hard ARO has been in terms of P / L financial results. The Company recorded losses during the period 1997-2004, a maximum of these operating losses representing the year 2002 (of 95,588 thousand RON), the main cause of these losses being the limited volume of activity and fixed cost (electricity, natural gas, the expenditure of labor, damping, etc.). The most significant operating expenses are expenditures on raw materials and consumables, personnel expenses, expenses on external services, and in particular, costs related to the passing on costs of interest and penalties claimed by state bodies for non-payment of their obligations. The loss of RON 20,000,000 at the end of 2004 further aggravated the situation of the state, which had great difficulties in privatizing ARO, pushing the company into the arms of a dishonest entrepreneur from the US.

Figure 4. ARO - Evolution of Employees number vs. Salary Cost

Figure 4 shows us the evidence of an unsatisfactory cost management, because while many employees were fired, unperformed management increased the cost of wages, paying large amounts inefficiently to people in at least dubious relationships with the factory. While in 1995 staff costs represented 25% of the 2004 production, it was 53% of the products sold. (values in thousands RON). This has led to a critical situation since in 2004 the labor cost reached 52.6% of the value of the production (see Fig. 5).

Figure 5. ARO-Evolution of Production vs. Salary Cost

DACIA Case Study

Dacia began his story in 1966, with the construction of the Mioveni Automobile Plant and in 1968, it was started to build a first national car, Dacia, based on an agreement between Renault and the Romanian state as cited from Dnistran (2015). Nowadays Dacia is one of the five brands in Renault holding, exporting cars to all continents of the world. The research sources behind our analyses of Dacia were mainly the annual financial statements and the annual report of the Board of Directors (2012-2016) quoted on the company's official website (www.daciagroup.com, 2016). To these sources, we added information that was taken from the financial accounting reports of the analyzed years, respectively 2012-2016.

Figure 6. Dacia-Main Indicators Evolution

All the indicators we have calculated in the case study look great, they illustrate good financial management, which could have happened because the factory was managed well in all respects with an outstanding operational and commercial risk management.

Figure 7. Dacia-Evolution on Equity

The total Assets of Dacia have evolved very well, increasing year by year, steadily, at a rate that has grown by 21% over 4 years we analyzed. In the following figure no 8, the substantial difference between Total Assets and Fixed Assets of RON 41,811,462 shows us without a doubt that current circulating assets have a high value, indicating an excellent return on capital and shows an annual growth trend

Figure 8. Dacia-Evolution on Assets

Operating expenses also had a growing trend, but they were lower than revenues, so the company earned operating profit in the period 2013-2016, the trend was positive from 429 million lei in 2013 to 532 million lei in 2016.

The evolution of turnover was slightly increasing, so in 2014 the turnover was RON 18,833 million, 2.34% higher than the one realized in 2013 when it was RON 18,402 million. In 2016 the turnover was RON 20,765 million, 8.4% higher than 2015 when it was RON 19,165 million. The Income from operations had a turnover-like evolution.

Figure 9. Dacia-Evolution on Revenues and Expenditures

Net profit increased from RON 3,370 million in 2013 to RON 4,560 million in 2016. The company had a favorable evolution that led to the continuous development and growth of the enterprise. Evolution of the number of staff was from 14,114 employees in 2013 to 14,001 employees 2016, so, the number of employees was constant during the analyzed period with a very small fluctuation, normal, but not upward, although production has diversified and steadily increased. This evolution has also allowed steady increases in labor productivity, once again highlighting sound financial management. The year 2016 reveals a tremendous increase over the past years in operating income, but proportionally and in fiscal value, which represents payments made to the state's fiscal budget, as we have seen from the AVAS Activity Report (2016), a government agency that deals with the use of state assets.

Conclusions and discussions

In the present chapter, we aim to verify whether the research done based on the two studies as a pair case (ARO and Dacia) gives us sufficient scientific and empirical arguments to conclude with a high probability that the research hypothesis is confirmed. We started with the main idea that we have checked, namely that a company's chances of success grow when an efficient management runs it. A very good financial risk management can make a difference between success and bankruptcy. Clearly, the research method used, namely the case study based on two companies that were created by the state many years ago, functioned in the centralized state economy in a similar way, provided scientific evidence and arguments that confirmed the research hypothesis.

We used in the case study research tools subordinated to the chosen method, derived from it, namely direct analysis of sources of information, analysis of financial and accounting databases, interpretation and processing of financial and accounting reports by graphic means, etc. All these research methods and investigative tools have led to clear conclusions as in the ARO case. The financial disaster occurred due to the lack of interest of the shareholder (the state), who appointed an incompetent manager's positions without real management skills. They did not put the company's interest first, did not worry about the correct and effective financial risk management and pushed ARO into bankruptcy. That, after they sold the factory negligently to a ghost company that decimated it in pieces for its own sake.

Through an identical but mirrored analysis, Dacia presents itself as a successful car factory, whose production indicators, accounting, operational, and efficiency and effectiveness indicators show year after year more and more.

Bocşaru (2016) argues that the growth of turnover in 2016 was driven by import and export markets. "As far as export is concerned, we have had a very good performance on the European market, but also on the markets in Africa and Asia, which makes exports this year to be about 90% of the turnover." Since 2000, the investments made by Renault Romania Group amount to 2.5 billion euros, being investments in new products (vehicles, engines, gearboxes, mechanical components) and investments in increasing the competitiveness of the processes production (social conditions, capacity increases, automation processes, quality and cost reduction). We obviously believe that the hypothesis built at the beginning of this research is confirmed, and success is due to good decisions to properly manage financial risk.

We can conclude that not many organizations spend time and money with cutting-edge technology, innovative, to meet their profit and the performance needs. Usually, every company uses the best measures available more than a couple of procedures for their business: e.g. financial reporting. Thus, the proactive metrics management solution could meet easily their indicators of the performances' criteria or from the different sources in the same company (Kernzer, 2017, p.332). Nevertheless, in the case of Dacia, it results from the analysis that the extraordinary results, a turnover of 3% of GDP and the number one company in terms of export, was achieved through real work, competent management, and moral basis.

If we allow ourselves to look retrospectively, the risk profile of ARO and Dacia companies was almost at the same level at the beginning of the 90's. There the corporate risk management had been conceptually different from the function of "trading/risk-taking" because the "corporate risk management does not focus on sporadic and opportunistic hedging based on an idea that the manager has at a particular moment... this activity must have a separate income statement, have objectives, be monitored and so on - in other words, be a classic trading/risk-taking activity" (Garcia, 2017, p.8). Cars manufactories are usually exposed to various kinds of risk, not only to the market risk, the exchange rates, the inflation and fluctuation of national currency (RON) in comparison with US dollars and Euro, the derivation to hedge-currency, interest rate or change in commodity prices risk – by forwards.

Looking back, we think that there was not only ignorance of the management, but it was greed and bad intention. We conclude that lessons to be learned by anyone

reading this research are that financial risk management in state-owned companies remains a thorny issue, and it has not been fully addressed today either. The authors of the paper acknowledge the limits of this research, namely that the case study has encountered difficulties due to the fact that ARO is bankrupt and the existing database is limited. On the other hand, it is difficult to extrapolate the findings of a two-nation research into a national economy, but in future work, we propose to do other case studies from various industries.

THE CHALLENGES OF PERFORMANCE ASSESSMENT IN ROMANIAN STATE-OWNED ENTERPRISES

Ionela MUNTEANU

Bucharest University of Economics Studies
10 Tache Ionescu St., 010352, Bucharest, Romania
consultant.munteanu@gmail.com

Abstract. *The process of setting proper key performance indicators to managers of state-owned enterprises is a critical issue in developing the premises for increasing the efficiency of the public sector activity, as well as the management's accountability. Managerial strategies and the impact of the decision on business achievements are actively debated in nowadays literature. The necessity of law amendments is of constructive interest for several perspectives, such as improving the global regulatory framework and, at the national level, for state control bodies recommendations. The Performance Measurement Mechanism presents a dual approach and a two-way challenge. On the one hand, quantifying performance implies establishing measurable managerial obligations in order to achieve business profitability and strengthen the process of economic and efficient use of resources. From a managerial perspective, fulfilling the imposed criteria may present a motivational challenge, because the level of accomplishments directly determines the level of remuneration. The "final beneficiary" who may actually acknowledge the fulfillment of goals and the quality of the services provided by SOEs are in fact the ordinary people who experience and appreciate, ultimately, the effect of the managerial strategies and the outcome of the managerial act. In this context, the method of setting key performance indicators is of paramount importance. Our paper proposes a performance quantification model in the Romanian SOE field, which allows a fast and intuitive identification of a minimum set of performance criteria, adaptable to the specifics of the enterprises' activities. Through a methodological approach to regulations, considering a representative pool of Romanian SOEs. We believe that the precursors of a balanced configuration of the basic key performance indicators in SOEs sector can be set. The study is significantly important from the perspective of the calculated results, which sets the premises of developing future analyzes. The proposed model strives to become a valuable reference in formulating key performance indicators in the Romanian SOEs.*

Keywords: *governance monitoring; key performance indicators; cluster analysis; SOEs.*

Introduction

Transparency and accountability are prime topics directly related to the managerial decision-making process. The quality and values of long-term strategies are highlights and precursors of sustainability and business development potential. In such a context, the managerial responsibility is being analyzed through diverse and continuously expanding concerns, along with the need to implement performance measurement techniques able to bring comparison grounds in a rapidly expanding economic society.

The powerful link between law and useful monitoring models that can "breathe life into the duty of care" inspired Dent, in 1981, to encourage the "revolution in corporate governance" and to draw concern to the effects of managerial passivity on company

goals. Although courts of law are empowered to enforce certain legal standards to board members or management factors when flaws in duty are being denounced, Dent draws attention to the importance of consciousness in hierarchical monitoring. His study reveals that neither the market, nor the law has the adequate means to enforce monitoring, but the function of board monitoring models (Dent, 1981).

Furthermore, the nexus between corporate governance and financial performance has been documented (Westphal, 2002; Leblanc & Gillies, 2003). The linkage between these two concepts gains special significance when it comes to public sector entities since state-owned enterprises (SOE) gain more and more attention. The contribution of SOE in the gross domestic profit of every country is significant (Bruton et al., 2015; Bernier, 2015), hence the debates on the decision-making process and corporate efficiency need to be thoroughly analyzed (Clatworthy, 2000).

Under the OECD's recommendations, the European countries contributed to the implementation of world practice standards that allow harmonization of public management assessment. The ultimate aim of the "governance revolution" was to initiate a comprehensive legislative reform process to harmonize internal regulations within European countries, with special regards to the public sector. (OECD, 2004)

Literature focusses on further expanding the contribution to a better understanding of the governance mechanism (Kettl, 2000), by addressing studies to internal audit processes and role (Ferry et al., 2017), control systems, external auditing and auditing committees (Deloitte, 2013). Almquist et al. observe various studies conducted in corporate governance and accountability assessment and signal the need to further investigate the relationship between various elements of the public governance sector. (Almquist et al. 2013)

Based on these assumptions, the current study explores the possibility of creating a primary set of performance assessment model for the public sector, by combining law specific requirements with methods of setting key performance indicators and benchmark indicators. The study is conducted on Romanian SOEs, based on the public information available on the site of the Romanian Agency for Fiscal Administration.

Reflections on performance assessment models

In time, monitoring models have been analyzed and developed from various perspectives. The assessment objectives directly influenced the techniques and measures of models, together with the concern for the development of performance governance frameworks in organizations. Thus, the monitoring model specifics are accustomed to the sector where the company activates, the organizational structure and shareholders' interests, the typology of provided services or activities, the economic context and controllability. Starting from the requirements and projected outcomes of monitoring models design, the usefulness of framework assessments has been long debated. Various studies reveal that sometimes managerial assessment models can prove to be useless or untrustworthy if listlessness or secondary interests of managers come to pass (Dent, 1981; Butcher, 2000).

The "traditional model" of corporate governance assessment is based on the principle that the affairs of an entity are managed by the board of directors, not by the executive

officers/directors (Eisenberg, 1976). The former concept has evolved in time, thus being generally accepted that business is managed “under the supervision of” board managers. Several studies concentrated on the importance of proper settlement of managerial duties and competence in setting independent assessment models: primarily, the law is the starting point to regulating conflicts of interest and may clearly settle statements of duties (Sugarman, 1999).

The perspective of stricter regulations may enhance and better settle the issue of directors’ duties (Butcher, 2000; Elson, 2004; Slorach, 2004). A figurative statement clearly attacking the lack of active implication or passivity of managers was made by Irving Olds, the Chairman of US Steel: “Directors are like parsley on fish – decorative but useless”. The critics were made in a period when controversies arose with respect to the issuing of a Canadian report on corporate governance, that drew controversial responses for the lack of proper attention to real governance problems and for the politicization of corporate managers (Leblanc & Gillies, 2003).

The “modern” mechanism of governance assessment proposes a series of techniques meant to allow the harmonization of company outcomes in order to contribute to a better understanding of standardized solutions to better achievement of economic goals.

In the public sector, the performance assessment techniques consist of budgeting, balanced scorecard, controlling, strategic planning and monitoring (SWOT analysis) or other. Literature show there is a strong belief that key performance indicators (KPI) are critical for improving the effectiveness of governance systems and are a mean that actively contributes to achieving company targets.

The quality of an appropriate group of key indicators is testified by their ability to adapt to business specifics and to correctly appreciate the value of the managerial act. At the same time, previous studies demonstrate the contribution of the qualitative preliminary analysis of the optimal methodology to set key performance indicators and benchmark indicators to a good design of the obtained results. One of the most important factors that influence performance is the human resources and their understanding of the role and effects of a professional management. (Grigorescu, 2008; Grigorescu & Bob, 2010)

Are monitoring models necessary and useful?

The question on necessity and usefulness of managerial assessment seems to have a straightforward affirmative answer. Nevertheless, the current Romanian context, the political influence on public governance constantly debated in media and the day-to-day reality in public services seem to suggest the to further reflections before giving a straight answer to such question.

The current study highlights the raising awareness of the Romanian public opinion on the role of performance assessment in the public sector. At the same time, we carefully analyze the evolution of the legal framework in Romania regarding the state-owned enterprises, the strategies and the objectives projected for corporate governance in the public sector, the general economic context, as well as the stratified approach of the economic branch of the selected SOEs pool. The findings are interpreted and reunited in order to set the basis and explore the possibilities of formulating the key performance

indicators in an efficient and structured way. We actively aim at meeting the general requirements of transparency, SMART analysis, alignment to business objectives and operations and to address a dedicated section to the enterprises' specifics.

The principles and benefits of a quality management system are anchored in the competitive evolution of financial and non-financial results reported by the Romanian pool of SOEs. In order to comply with OECD regulations, Romania struggled to implement, at least on a formal basis, the legal framework for managerial assessment in public entities. The formal approach on managerial measurement standards was long criticized, even by the state control institutions, that reported little improvement in public sector and highlighted the insufficient political support, lack of transparency in public governance or vision opaqueness in evaluating the force of managerial assessment (European Commission, 2018; Ministry of Romania Public Finance, 2014).

In Romania, the legislation regarding the need to implement corporate governance in public entities has developed over time in the sense of harmonization with the requirements of the European Union. Thus, since the Emergency Ordinance no. 109/2011 on corporate governance in public enterprises, the public interest for the importance of participative governance began to increase. Furthermore, the regulations extended the requirements on management monitoring procedures, by setting milestones regarding the assessment process. A first step in this direction was to settle mandatory procedures in order to formally address the independence of managerial appointments. Also, in order to set the grounds for managerial monitoring, regulations regarding key performance indicators were implemented on a two-basis perspective: on the one hand, the key performance regulations were set with the purpose to increase the achievement of corporate goals and, on the other hand, KPY was supposed to become a motivational remuneration objective for the appointed managers.

The following table synthesizes the main regulations regarding governance measuring framework in Romania:

Table 1 Regulatory framework regarding corporate governance in Romania
(author's compilation from Romanian legal regulations)

Main governance regulatory requirements	Regulations on benchmark and key performance indicators
- the general framework and selection conditions for the members of the management of public entities were settled - publishing governance reports became compulsory - the appointment of managers in public entities may be possible only on the mandate contracts basis - obligations regarding advertising of the identity and professional training of management	Emergency Ordinance no. 109/2011 on corporate governance in public entities
- settling selection criteria, conditions for shortlisting for up to 5 candidates for each post, ranking, final appointment procedures - establishing the financial and non-financial key performance indicators and the variable component of the remuneration of the board of	Decision no. 722/2016 regarding the methodology and norms for Ordinance no. 109/2011

Main governance regulatory requirements	Regulations on benchmark and key performance indicators
directors or, as the case may be, the benchmark indicators of directors	
• reporting obligations regarding the state of implementation of corporate governance standards • defining areas of interest and reporting deadlines • in order to ensure monitoring of corporate governance, managerial requirements were established regarding broadcasting information on how to proceed with the selection of directors, the approval of management plan, advertising annual reports to ensure transparency, auditing financial statements, performance indicators and about the variable component of remuneration	Decision no. 2874/2016, repealed by Decision no. 1952/2018 for monitoring Ordinance no. 109/2011

The concept of corporate governance in the Romanian public sector extended the duties of shareholders. The new regulations brought transparency and hierarchical reporting obligations for managers and set the grounds for governance accountability. Key performance indicators seem to become an active ingredient to assess governance efficiency, although the consequences of flaws in duty are not very clearly determined. According to current regulations, key performance indicators have also a motivational purpose and should be settled within the mandate contracts of board directors in order to determinate the variable component of managerial remuneration. Nevertheless, if such a variable component is not defined within the managerial along with the appointed key performance indicators, the law seems to not propose a sanction or monitoring procedure.

Although complex and highly promising in appearance, the corporate governance regulations brought little visible improvement in public services and governance policies. Media also contributed to the monitoring process, by loudly debating various situations of illegal human resources procedures in public entities or faulty managerial appointments. Gradually, the public opinion became aware of the efficiency requirements and transparency principles of corporate governance. Still, the positiveness of such awareness confronts itself with “but”. The population becomes aware, but the lack of regulations regarding the faulty implementation of corporate governance standards still raise an obstacle in achieving a value-based culture in public services or public resources allocation.

The author considers that the primary need for a better improvement of governance monitoring and managerial assessment derives precisely from the real need to acknowledge the importance of legitimate regulations in public sector and of a proper undertake of consequences in faulty managerial duties.

Rudimentary monitoring models, nonrealistic analysis of corporate activities or context, political or personal interests, scarce details regarding managerial duties or lack of maturity in risk analysis are issues that require thorough solutions. The proper vision to provide a satisfactory response to such problems is the trigger to formulating

effective monitoring models that can bring added value to corporate operations and thus to reside in service improvement and economic progress.

Developments in public measurement models

The main goal of measuring the performance of public enterprise management is to increase efficiency in public service, to develop new strategies in the better procurement and allocation of public resources and strengthen the participative governance. Measuring performance can also bring a breakthrough in better organizational structuring, client satisfaction categorized as people's satisfaction when it comes to publicly owned companies and, furthermore, a better way of life.

The process of setting performance indicators is closely correlated with the public entity's mission, its objectives and the actions proposed by management while considering the available resources.

According to current regulations, the classification of performance indicators is done in two broad groups:

- benchmark indicators that are established in relation to the activity of the public enterprise. These indicators allow the company's results to be measured against the targets and make it possible to compare the enterprise's indicators with those of other similar companies.
- key performance indicators that are set for managers and according to which the variable remuneration component is allocated. Key performance indicators also consist of financial and non-financial indicators (which are operational and corporate governance).

On a graphical basis, the first steps in developing a monitoring model in public entities are to set the key performance indicators and the benchmark indicators, as in Figure no.1.

Figure 1. The process of managerial assessment

From the above figure, we can observe that performance indicators are set on a hierarchical basis, downwards. The defining criteria for setting proper performance indicators should consider the corporate mission, governance objectives and resources of the public institution following a rigorous analysis of the action plan or management of the subordinate institution's management. Among the key criteria underlying the

establishment of a set of effective indicators are the premises of transparency and the acknowledgment of independent research. Proper transparency procedures give access to information to every interested party and create possibilities for every individual to conduct monitoring procedures on specific data.

According to Romanian regulations on free access to information of public interest, public entities have the obligation to submit an annual activity report from which interested parties may find out information on performance indicators and their degree of achievement. Advertising the performance report is a legal obligation for managers derived from the principle of decisional transparency. Advertising the performance report is mandatory, also by publishing it on the public institution's website.

Figure 2. Typology of KPI (Source: Government Decision no.722/28.09.2016)

The process of selection of key performance indicators allows the governing entity (or the higher hierarchical institution) to choose from a high number of indicators. The regulations advice on selecting a set of specific KPI from each category of financial, non-financial and governance corporate KPI (Government decision no.722/2016). Nevertheless, the Romanian National Agency for Fiscal Administration (hereby called the Romanian IRS), the institution empowered with the centralization of KPI data, shows that not every reporting public entity has been appointed with KPI from each category: certain entities have not been appointed with corporate governance KPI, because such indicators may already be perceived as requirements according to law. (ANAF, 2016)

Establishing indicators is a dual challenge. A set of effective selected indicators can actively contribute to the efficiency of the subordinate entity's activity and, at the same time, it is supposed to be an important motivation tool for its management.

The main focus of the current study was to analyze whether the so far used KPIs in Romanian SOEs may be linked by relevance into incentives to validate the principle of continuous activity or into typologies that may be attributed to certain domains of

activity. The premises of the study were that financial KPIs may represent reliable indicators to predict or assess the managerial accountability concerning business development.

Previous studies demonstrated that using Clustering techniques, relevant observation may be obtained regarding the relationships between KPIs (Guo et.al., 2016), with specific attention to corporate governance KPI (Kocmanova and Simberova, 2012). In Romanian literature quantitative studies on corporate governance, KPI needs to be further developed in order to provide typologies and reliable monitoring models useful in the SOEs sector.

Methodology of research

We used all the available Romanian IRS economic reported indicators, providing 1065 local state-owned enterprises in 2013, increasing to 1381 in 2016. Based on the analyzed indicators, the methodological approach of the current study was developed in two main stages. In the first stage, we tried to find out if the reported key indicators centralized by the Romanian IRS can be categorized into significant typologies depending on the active or inactive status of the reporting SOEs. According to Romanian IRS, the reported indicators can be categorized into indicators reported by active SOEs and inactive SOEs, with or with no comparable data recorded in their financial statements during the analyzed period of time. The Non-Hierarchical Cluster Analysis was used with SPSS software. The in-active firms were considered to be the SOEs with obsolete financial difficulties, as the SOEs in insolvency procedure or that was declared bankrupt. During the next stage of research, we also tried to analyze if certain KPIs can be identified to be most likely to be utilized depending on the domain in which active companies activate, based on all the available information collected from the 1186 active SOEs in 2016 (out of a total population of 1381 across all local SOEs). The available data were compiled into representative KPIs for assessing business profitability. The Hierarchical Cluster Analysis was used in this stage.

Discussions and results

In order to achieve a robust analysis of the selected data, this study focused on identifying similarities between reported KPIs in order to observe patterns or typologies that may become specific to active or in-active firms. The economic indicators were observed in order to assess how groups of KPIs may be related to each other on premises of activity continuation. A K-Means Cluster Analysis was performed. The variables used in the analysis were the active companies with comparative data within their reported financial statements (coded SOEs active CD), the inactive companies with comparable data in their financial statements (coded SOEs inactive CD), the active companies with no comparable data (compared to previous reporting periods) in their financial statements (coded SOEs active NoCD) and inactive companies with no comparable data in their financial statements (coded SOEs active NoCD). The companies with no available data were removed from the study. The research aimed to obtain a three-cluster standardized result.

The observed indicators for active companies differed substantially in comparison to those reported by inactive companies, both for categories of companies with comparable or non-comparable data in reported financial statements (for example,

active companies reported positive earnings before taxes, while inactive companies reported negative earnings before taxes). Thus, for a reliable result of the analysis, the data was standardized by calculating Z-scores for the considered variables.

On a standardized scale, the SPSS calculated data as per Table 2. The results show that cluster one has lower results (also negative on a standardized scale) for active entities with comparable data than clusters two and three. Similarly, cluster 1 has lower negative results on a standardized scale for inactive entities with comparable data than clusters two and three. From the calculated Cluster centers, it can be observed that cluster three for inactive entities with no comparable data in their financial statements has the highest number of results for the same category than the other two clusters. The K-Means Cluster Analysis conducted to mixed results of calculated standardized Zscore. As per figure 3, the third cluster does not seem to gather relevant results with regards to similarities between the Zscores calculated for KPIs attributed to this cluster. The obtained results were not conclusive as to allow a standardized statistical result able to present incentives on a typology of KPI in active or inactive SOEs, considering reported KPIs compiled from their financial statements.

The second stage of the research compiled the financial indicators reported by SOEs in 2016 and calculated corporate governance financial KPIs, used according to Romanian law during the process of settling the variable component on remuneration for SOE board of directors. The compiled profitability KPIs that could be determined in this stage, based on available data (ANAF, 2017) are:

Table 3. Financial KPIs for profitability assessment (author’s compilation)

Financial KPI – profitability assessment	Calculating formula
Earnings before interest and taxes marginal (EBIT marginal)	EBIT / Turnover
Earnings before interest and taxes and amortization marginal (EBITDA marginal)	EBITDA / Turnover
EBITDA per equity	EBITDA / Equity
Rate of return on capital	Earnings before interest (EBT) / Equity
Gross result in total sales	EBT / Turnover

The study considered the compiled data as variables obtained in different domains of activity and analyzed them using Hierarchical Cluster Analysis. The previous statistical check was not considered in this stage, with the intent of observing similarities between

the calculated variables that would allow highlighting a typology of indicators which would be more suitable to use in certain business domains (Andel & Hebak, 1987).

The limitation of the study consists primarily of the limited data available regarding public sector KPIs. Although the current regulations settle compulsory requirements on the transparency of KPIs, remuneration and performance reporting, the current practice in Romanian SOEs shows that compliance in this sector is scarce and, in most cases, basically formal.

The cluster analysis relied on centroid linkage method in order to be able to obtain clusters of different dimensions that may offer incentives on KPI appropriateness in relation to different business domains. Previous studies reveal that underlying models regarding KPIs in the public sector have been developed over time, but still, the policies of governance require flexibility and thorough local economic assessment in order to become effective. (Shen et al., 2015)

The calculated data are hereby presented in figures 4 and 5.

Figure 4. Agglomeration Schedule Coefficients

Figure 5. Dendrogram using Centroid Linkage

The calculated coefficients during hierarchical clustering model showed that the general assessment of KPI in relation to all business domains may not result in reliable profitability KPIs clustering. In Figure no.4, the Agglomeration Schedule Coefficients statistically compute how much new data is provided by each additional cluster.

In order to verify if the computed information is trustworthy, the graphical representation of coefficients was furthermore processed in order to provide a bigger picture of the highlighted clusters. For a better use of such purpose, squares have been added to the linear representation of coefficient obtained with SPSS program. The designed squares show that a two-cluster division of KPIs may provide more data than a three-cluster model, but for such information to be of better interest, than a five-cluster model may be more appropriate. The pattern observed in figure no.4 is also supported by the dendrogram in Figure 5. The visual interpretation of hierarchical clustering suggests that a reliable link between profitability KPIs and business domains may not be generalized. The measuring model for choosing appropriate KPIs in SOEs seems to be more effective when the appointment of profitability KPIs is sustained by a

comprehensive analysis of the SOEs' business context, on environmental risk, regulations, client satisfaction, business risk, and market conditions.

Conclusions

The current study shows interesting outcomes related to the design of corporate governance assessment models in Romanian SOEs. The value of the findings resides in the fact that real compliance with corporate governance regulations in setting key indicators may actively contribute to public services improvement and effective procurement and use of public resources. The obtained results, together with the current governance practice seem to suggest several possible scenarios:

- the procedures for setting KPIs should have an important impact on managerial remuneration together with corporate development prospects. In reality, the law does not sufficiently discern between the purpose of compensation and any injunction for disregard of settlement for variable remuneration in mandate contracts. In other words, according to Romanian IRS reports, although there have been observed various situations in which the KPIs have not been achieved or when variable remuneration has not been decided (ANAF, 2017), the measures undertaken by authorities in order to correct such situations are not very clearly disseminated.
- The measuring models should contain KPIs in all required fields: financial and non-financial. Also, for the non-financial KPI projection, both operative and corporate governance KPIs should be considered. Day-to-day reality reveals that corporate governance is not always a KPIs settlement concern (ANAF 2017), thus implying a formal feature to the regulations in force. The managerial accountability should be measured not only through financial results but also by directorial implication, vision, ethics, and professionalism.
- The financial KPIs analyzed, although limited in detailed data and not completely reliable for general assessment, suggest a stringent need to enhance transparency and public reports in Romanian public entities. In broad terms, the financial KPIs appointed without a proper support from non-financial KPIs may be directly affected by potential error or fault in financial statements. Also, in SOEs with long-term profitable activity, financial KPIs appointed to new managers may not be very relevant or accurate, because the activity may follow an inertial trend, with no necessary active implication from assigned new managers.

The current study strives to raise the interest in developing future research on the relevance of governance assessment in the public sector, based on the importance of cost-effectiveness and public service to quality of life. The performance assessment models of SOEs should not be considered an issue that requires addressing, but a challenge that eventually will lead to development. The further concern should also be attributed to enlarge dataset for accountability or transparency KPI. The augmentation of case study literature and development of econometric models for prediction purposes may also be of great value in the SOE sector.

GOVERNMENT EFFECTIVENESS BETWEEN RULE OF LAW AND SANCTIONS POLICY

Bucharest, Romania

adrian.vintilescu@incir.ro

Abstract. *Government effectiveness dimensions can be considered interdependent. It may be reasonable to believe that better accountability mechanisms lead to less corruption or better governance is given by a higher level of corruption control. Classical theories that address the effectiveness of sanctioning policies developed by Becker and Tullock state that the increase in sanctioning policies reduces fraud tendency. The cost of maintaining control and punishment policies is growing bigger due to the psychological changes of individuals, which involve additional and costly steps, both in terms of cost per se and increasing cognitive dissonance over rules. If we plan to observe this phenomenon, we can simply look back only 20 years ago in Italy (the "mani pulite" nationwide judicial investigation into Italy's political corruption and especially in the later developments). Moreover, we can analyze the current situation in Romania nowadays when we notice that the fight against corruption is difficult to sustain in the long term after a period of strong development. Similar situations have been described in theory during the experiments of Robert Sears in which people who have been subject to higher penalties for committing an act prohibited by the rules tend to commit the offense more often compared to those who were undergoing milder punishment. The models which use the cognitive dissonance theory to determine the effectiveness of sanctions policies, such as those of Akerlof and Dickens, based on Sears's experiments, explain that the internal decision not to commit an illegal act lies in the rule of law belief and enforced regulation rather than in the sanctions policy severity. Based on these theories, the paper aims to carry out a quantitative analysis of some factors that contribute to the government effectiveness increase. The analysis was performed using the worldwide governance indicators (WGI) developed by the World Bank and took into consideration the WGI indicators dynamics, rule of law and corruption control, and the way in which these two indicators influence the dynamics of government effectiveness. The research data included 32 countries for which the evolution of corruption control and rule of law indicators can be characterized by a significant trend. For each country have been calculated the trends in the indicators evolution for the period 1998 - 2016. The authors selected only those countries where the determinative factor was high, which means a significant trend of the corruption control indicator. A first conclusion of the paper highlights that the corruption control dynamics are directly correlated in the short term with the rule of law and government effectiveness dynamics which confirms Becker and Tullock's sanctions policy. The influence of cognitive dissonance on Sears's experiments (and also the models of Akerlof and Dickens) result from the second conclusion of the study, which emphasize that the increase in the difference between the two indicators tends to affect the government effectiveness dynamics. The conclusion of the*

paper is that the growth rate of corruption control should be roughly equal to the rule of law growth to achieve a maximal government effectiveness.

Keywords: *rule of law; control of corruption; government effectiveness; behavioral economics.*

Introduction

According to Tullock and McKenzie (1981) and Becker (1968), sanctions have the ability to prevent crimes. The concept is part of standard economic theory where, if the cost of an item is increased its consumption shall decrease. Accordingly, if penalties will increase in efficiency the tendency to commit an offense shall also decrease. A first element to be taken into account is the cost assigned to identify corruption cases (monitoring, tracking etc.).

The above-mentioned economists have previously applied price theory to explain crime and punishment. These models suggest that, by increasing the cost of crime, society can reduce the number of crimes committed. Consequently, by increasing the probability of detection or punishments imposed for crimes, the number of crimes committed can be reduced. However, psychological experiments suggest that another factor is worthy of consideration: self-motivation to obey the law.

Motivated by cognitive dissonance theory, psychologists have found that a threat of severe punishment can, once removed, increase the probability of a crime being committed. In contrast, removal of a weaker punishment led to a smaller increase in the probability of a crime being committed. Akerlof and Dickens (1982) explain that these studies suggest that individuals who decide not to commit crimes with small punishments are driven by an internal belief in following the rules. In other words, they create an internal justification for their decision to comply with the rules. These individuals do not just compare the costs and benefits of crime; they are strongly motivated by their initial belief in following the rules. In order not to get into cognitive dissonance people can control their beliefs to some extent, given the information regarding the rules around them which persist over time (including customs and legal regulations).

Therefore, people enter into cognitive dissonance when knowing that by committing an offense they disagree with the rules around them. When the power rules get deeper into people's conscience then increased corruption control becomes of secondary importance compared to trust and cooperation which rather lead to economic growth. Therefore, self-motivation to respect the law and to comply with the rules is an important factor to keep in mind on the long run, besides implicit costs of anticorruption measures, as they develop an important element for economic growth, namely trust and solidarity.

The research question is whether increased control and punitive measures are effective or not in cases where there is motivation to abide by the laws (Dollar & Kraay, 2002).

The authors also note that governance dimensions should not be thought of as being somehow independent of one another. One might reasonably think, for example, that

better accountability mechanisms lead to less corruption, or that a more effective government can provide a better regulatory environment, or that respect for the rule of law leads to fairer processes for selecting and replacing governments and less abuse of public office for private gain. In light of such inter-relationships, it is not very surprising that the six composite measures of governance are strongly positively correlated across countries. These inter-relationships also mean that the task of assigning individual variables measuring various aspects of governance to the six broad categories is not clear-cut.

On the other hand, the cost of maintaining a trend of increasing development for control and punitive policies is becoming higher due to psychological changes in individuals (not assuming responsibilities, lack of communication) that involves additional steps which cannot be developed at the same pace, both in terms of cost and cognitive dissonance growth against the rules. Similar situations have been described during the experiments of Robert Sears in which people who have been subject to higher penalties for committing an act prohibited by the rules tend to commit the offense more often compared to those who were undergoing milder punishment. In fact, social and legal rules have a time dynamics dependent on collective conscience.

For example, in 2009, British Prime Minister Gordon Brown has apologized for the "appalling" treatment that mathematician Alan Turing had undergone, for breaking a social norm of the time. The apology came after all the British population demanded that the recognition of the "tragic consequences of prejudice that ended the career and life of this man and that the gratitude we all owe to him make the inhumane treatment he had undergone to look even more awful", said Prime Minister Gordon Brown. The state norm at that time which was difficult to accept resulted in the loss of long-term development and technical progress that generates growth.

Another eloquent example is that in developed countries there are shops where customers choose their merchandise, leave the money in the mailbox, as much as each of them appreciates and leave (the experiment proved that people do not undervalue goods). Suppose that in a town where a similar local store exists, migrates a group of refugees (who have a different perception of rules), enter the premises and do not pay for the products.

Apparently, the imposition of control measures seems efficient, such as the hiring of a seller, but this approach for control causes a cost, both by salary or monetary costs but also due to the cognitive dissonance of people who were once accustomed to that rule (Thaler, 2005). As we shall see, if the store had existed in the country of the immigrants group, increased control over corruption has a direct connection to economic growth, as it generates a consistent business environment and correct distribution of the tax burden but also increases public revenue.

Hence, building national public policies must take into account punitive measures as well as building a stable set of rules, predictable and accepted (Georgescu, 2015). Depending on each country's development, certain factors determine the design of adequate public policies and government effectiveness.

The study aims to analyze the worldwide governance indicators (WGI) to deliver an opinion based on quantitative assessments and tools on the opportunity of public policy

measures, in the general framework of norms and guidelines in the rule of law area and the economic context. World Bank researchers have developed a series of indicators which classify countries according to governance quality by aggregating data from multiple sources available. Global indicators of governance corroborate perceptions of a significant number of corporations, citizens and experts who participated in the research in industrialized countries and in developing economies (Ramanujam et al., 2012).

The worldwide governance indicators are a long-standing research project to develop cross-country indicators of governance. The indicators are based on more than 30 individual data sources produced by a variety of research institutes, think tanks, NGOs, international organizations and private sector companies. They are based on 340 variables produced from 32 different sources, including providers of commercial information, studies of firms and households, non-governmental organizations and public sector organizations. The indicators defined by Kaufmann et al. (2007) are grouped into 6 categories, as follows:

1. *Voice and Accountability (VA)* is measuring the perception of a country's citizens being able to participate in choosing their government, freedom of expression, freedom of association and a free media.
2. *Political Stability and Absence of Violence (PV)* is measuring the perceptions of the likelihood that the government shall be destabilized or overthrown by unconstitutional or violent means, including political violence and terrorism.
3. *Government Effectiveness (GE)* is measuring the quality of public services and the degree of independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies.
4. *Regulatory Quality (RQ)* is measuring perceptions of the government's capacity to formulate and implement sound policies and regulations that allow and promote private sector development.
5. *Rule of Law (RL)* is the evaluation of perceptions regarding the extent to which agents have confidence in and abide by the rules of society, in particular, the quality of contract enforcement, the police, the courts and the likelihood of crime and violence.
6. *Control of Corruption (CC)* is the analysis of perceptions regarding the extent to which public power is exercised for private gain, including petty and serious forms of corruption, and state "confiscation" by elites and private interests.

There are several studies on the relationship between institutional structure, its characteristics, and the economy. These studies change according to the income status, institutional structure and the economic performance of the countries. In the studies performed by Kaufmann et al. (1999) on a sample of 150 countries, the scholars found out that there is a serious cause and effect relationship between rule of law and income per capita, literacy and infant mortality rate. Income per capita gap may be 3 times more in the countries not implementing the rule of law principles compared to the countries implementing it.

Nobel-winning economist North (1990, pp.97-112) who believes that short-term economic growth is possible without the rule of law requirement, argues that to provide long-term economic growth especially in dictatorial regimes, development in rule of law issues is required since North states that lack of property protection rights prevents capital investments which would help economic growth.

Furthermore, Keefer and Knack (2000) and Hall and Jones (1999) claim that there is a close and positive relationship between property rights and economic growth. Protecting property rights, taking them under the state guarantee and thus the increase in investment demand positively affect the economic growth as it is in technological and other various innovations.

Valeriani and Peluso (2011) made a panel data analysis for 181 developed and developing countries. As a result of the analysis, the authors stated that institutional quality has a positive effect on economic growth in developed and developing countries. Hence, generally, it can be concluded that with the rule of law increase in a country, social welfare and per capita income really increases in that country.

A number of studies in this field have used indicators in statistical analysis to explore the possible relationship between governance and growth: Neumayer (2002), Kaufmann and Kraay (2007), Meon and Sekkat (2005).

It is quite difficult to approach a comprehensive analysis because of the differences in public policy but also in countries development (Rigobon & Rodrik, 2004). Moreover, there are large differences between countries in terms of natural resources, regarding political or legal rules (Kahneman & Deaton, 2010, pp.1-5). Countries that have legal protection for investors, allowed the development of sophisticated financial markets, which increased the economy's ability to bear risks (Barro, 2003). Differences in the legal system or the degree of economic development are only part of the explanation.

In the presence of the factors such as corruption prevention and freedom of expression, the institutional structure has a significant impact on the economic growth. North (1990) defines institutions as: *"Institutions are the rules of the game in a society or, more formally, are the humanly devised constraints that shape human interaction"*. Institutional structure contributes to economic growth by providing use of resources in productive and efficient areas. Besides, corruption prevention, transparency, and accountability are also significant for the institutional structure to function efficiently and effectively. Rule of law principle, which is the cornerstone of democracy, is the greatest assurance needed by people both individually and as a society.

Dataset and the model

The variables used in this study cover the rule of law index, control of corruption index and government effectiveness index. Concerning the dataset used in the research paper, the authors analyzed 6 indicators for 181 countries that have been extracted from the website www.govindicators.org, and belong to the period 2004 - 2016. In the World Bank database, the aggregate indicators are reported in two ways: (1) in their standard normal units, ranging from approximately -2.5 to 2.5, and (2) in percentile rank terms from 0 to 100, with higher values corresponding to better outcomes.

A key feature of the WGI is that all country scores are accompanied by standard errors. These standard errors reflect the number of available sources for a country and the extent to which these sources agree with each other (with more sources and more agreement leading to smaller standard errors). These standard errors reflect the reality that governance is difficult to measure (Broda & Weinstein, 2004) using any kind of data.

To exemplify the data used in the study, the Figure 1 below presents the WGI evolution for Romania. Data representation for one country only provides a picture of the data used in the study. In a later white paper, the authors will perform comparative analyzes on the indicators evolution for different countries that will use qualitative analyzes of the particular causes that led to the indicators evolution.

Figure 1. Evolution of WGI for Romania (Source: authors own research results)

To achieve the paper objective, the authors will only analyze the countries where the trend of corruption control is significant and only for these states will be analyzed the influence on government effectiveness. We shall further consider the differences between control of corruption, government effectiveness, and rule of law and their evolution for the group of countries that have a significant corruption control trend. For the example considered, the results are presented in Figure 2 below.

Figure 2. Control of corruption, government effectiveness and rule of law evolution (Source: authors own research results)

In the first stage of the data analysis, the authors transformed each indicator's evolution according to the linear regression parameters compared to the calendar year $y = ax + b$ (represented by the dotted lines in Figure 3 below).

Figure 3. Control of corruption, government effectiveness and rule of law trend (Source: authors own research results)

Furthermore, the authors have numerically determined the coefficients (a) and (b) using specific spreadsheet calculation. Regarding the regression coefficient (a), the authors used the slope function which returns the slope of the linear regression line through data points in known_y's and known_x's. The slope is the vertical distance divided by the horizontal distance between any two points on the line, which is the rate of change along the regression line. As regards the (b) coefficient, the authors used an intercept function that calculates the point at which a line will intersect the y-axis by using existing x-values and y-values. The intercept point is based on a best-fit regression line plotted through the known x-values and known y-values.

Also, a third element considered was given by the indicators average that have the significance of a level indicator (for Romania this indicator is around 50%). The determinant coefficient that reveals the trend has been analyzed using the function RSQ which returns the square of the Pearson product moment correlation coefficient through data points in known_y's and known_x's. Accordingly, for each country, it is drafted a table highlighting the specific information.

In Table 1 below are presented the indicators: slope, intercept, average and RSQ for Romania. Similarly, the calculation below was performed for all the other 181 countries.

**Table 1. Calculation of WGI indicators trends
(Source: authors own research results)**

Romania	Slope	Intercept	Average	RSQ
Control of Corruption	1.108387	-2176.16	48.55555259	0.776413877
Government Effectiveness	0.447473	-851.684	46.46856615	0.269475244
Political Stability No Violence	-0.27281	600.819	53.24547746	0.043802454
Regulatory Quality	1.100658	-2144.33	64.87697199	0.729839274
Rule of Law	0.885221	-1723.54	53.24967024	0.792138608
Voice and Accountability	0.010938	38.64605	60.59955703	0.001058221

The table analysis reveals the following graphical representation of the functions (Figure 4 below). The graphical analysis highlights an upward trend of corruption control for the periods 2000 - 2005 and 2012 - 2016. If we compare the corruption control against government effectiveness, we notice that for the period 2014 - 2016, although control of corruption increases, government effectiveness is decreasing, even if there is a positive correlation between the two dimensions in the period 2012 - 2016.

The same type of relationship is also noticed in the period 2000 - 2005. The phenomenon defined in the introductory part of this paper can be described as follows: the increase in corruption control makes government effectiveness increase (which confirms Tullock & Becker's theory). The second phenomenon that confirms Sears's experiments took into consideration the cognitive dissonance theory, respectively, that a greater punishment could act as a hindrance due to a lowering effect of citizens' self-motivation to comply with the generally accepted rules.

Figure 4. Evolution of WGI indicators for Romania and the regression equation (Source: authors own research results)

This procedure explained for Romania's case was repeated for all the other 181 countries. As we have outlined, in order to formulate an opinion on the influence of significant trends in corruption control, the authors have chosen the cases with a significant trend, respectively the cases where the determinative factor in the corruption control is higher than 0.4, resulting in a low number of states that have met this requirement (32 countries).

For the data of the countries with a significant trend in corruption control, the authors analyzed the correlation of the indicators evolution described above. Basically, this research stage provides an opinion on the growth indicators correlation. Table 3 below presents the correlation analysis that determines the relationships between the data analyzed (a coefficient close to 1 indicates a direct correlation, a coefficient close to -1 an inverse correlation and a coefficient close to 0 signifies a lack of correlation).

Table 3. Correlation analysis (Source: authors own research results)

The government effectiveness (government effectiveness_a) slope is directly dependent on the corruption control slope and the rule of law slope, which confirms Tullock's sanctions theory. Thus, the increase in corruption control leads in the short term to increased government effectiveness. Likewise, it can easily be noted that the difference between the rule of law trend and government effectiveness (-0.63) is influenced in the opposite direction by the corruption control and rule of law trend, which means that when the legislator is trying to increase corruption control without the simultaneous increase of the rule of law there is a reverse effect on the increase in governmental effectiveness. This confirms Sears and Akerlof's theories and reveals the fact that a great difference between corruption control and the rule of law leads to a decrease in government effectiveness.

This issue is also evidenced by another advanced statistical analysis using the classification and regression trees. The analysis tool used in this research is CHi-squared Automatic Interaction Detection (CHAID). CHAID algorithm is a type of decision tree developed and introduced by Kass in 1980. The algorithm can be used for prediction, classification, and also establishing relationships among the various factors (Baltagi, 2001, pp.4-9). Decision trees usually provide simple and understandable results. One of the advantages of this algorithm is also the simplicity of results to understand and interpret. CHAID algorithm can be used for grouped qualitative and quantitative variables (Han, Kamber & Pei, 2011, pp.15-116).

In order to analyze the influence of the dynamics differences between control of corruption and rule of law, the authors defined an aggregate indicator given by (corruption control trend – rule of law trend) / control of corruption trend. Using the

CHAID algorithm for the panel data and considering the government effectiveness slope as the explained variable it can be noticed that in the particular case of countries with declining government effectiveness this issue is caused by the significant difference between rule of law and control of corruption.

Figure 5. CHAID classification trees (Source: authors own research results)

CHAID classification trees complete the covariance analysis with the conclusion that government effectiveness is also dependent on the difference between corruption control and rule of law trend.

The study highlights the complementarity of the effects of the anti-corruption measures that lead to an increase in short-term governmental efficiency. In the long run, if the government's measures are not accompanied by the rule of law acceptance, their effectiveness may be reduced.

Conclusions

The paper explains why the fight against corruption is sometimes difficult to sustain in the long run mainly due to the fact that the increase in corruption control is conditioned by its acceptance by all the population. If the goal of a public policy is to increase government effectiveness in the short term, then the increase in corruption control should be considered as a measure. If governments propose to maintain the trend of increasing government effectiveness, they should also consider the second component that is given by the rule of law growth as acceptance and cognitive consonance with laws and norms.

The study confirms the cognitive dissonance theory in determining the effectiveness of sanctions policies, such as that of Akerlof and Dickens (1982), based on Sears's experiments. Thus, a positive evolution of government effectiveness is due both to the sanctions policy rise, but also to the internal decision not to commit an illegal act, which rests in the rule of law and rules trust rather than in the severity of the sanctions policy.

The results of the research lead to the conclusion that the growth rate of corruption control should be correlated with the rule of law growth to achieve a maximal government effectiveness rhythm.

The limits of the paper are given by the limitations of the indicators used and of the analysis tools that only provide evidence of some indicators. The error margin of the indicators used in the quantitative analysis is high. Therefore, in subsequent studies, the authors will also analyze the qualitative aspects related to the countries analyzed using open data sources of information to substantiate the conclusions. Moreover, in future research, the authors will use other data mining algorithms such as neural networks to provide a suitable quantitative model and will present in a white paper the specific

particularities for various countries. Likewise, other variables will be included in the model, which will be defined according to the size of GDP or GDP/capita.

SUSTAINING E-PARTICIPATION FOR PUBLIC VALUE CREATION

Mauro ROMANELLI

*University of Naples Parthenope
Via G. Parisi 13, 80132 Naples, Italy
mauro.romanelli@uniparthenope.it*

Abstract. *Technology helps public organizations to sustain democracy restoring public trust, promoting public interest and fostering citizenship and collaboration in order to uphold participation in front of citizens that feel to be unheard and disenchanted by traditional representative and democratic institutions. Public institutions are facing the challenge of dealing with a mixed polity embracing elements of representative and direct democracy in virtue of democratic and participatory potential of information and communication technologies (ICTs) that contribute to driving public institutions and citizens to act as active co-producers of social, democratic and public value. Sustainability of public organizations relies on embracing information technology as a source that enables to connect public administration with citizens opening up to civic contribution and participation of civil society and people in order to make effectively participatory and democratic government agencies and public administration that meet the needs of citizens.*

Keywords: *information and communication technology; democracy; participation; public value; sustainability of public organizations.*

Introduction

The advent of information and communication technologies (ICTs) helps public organizations to sustain public trust, promote the public interest and encourage an active citizenship and collaboration by enhancing the interaction citizens-government in order to foster democratic participation (Denhardt & Denhardt, 2003; Vigoda, 2002).

As institutions having to cope a growing disengagement of citizens, public organizations should pay attention to causes of the decline of public trust by embracing the Internet and introducing ICTs in order to connect public administration with people, to communicate with citizens and to support the structures of democracy by enhancing participation of citizens as a means for creating and maintaining public value. ICTs contribute to sustaining the dialogue and partnership between citizens, clients, public organizations and various stakeholders as active co-producers of social, democratic and public value (Moore, 1995).

The aim of this paper is to elucidate how ICTs help to drive public organizations to behave as responsive and collaborative institutions proceeding towards sustainability by strengthening forms of democracy and encouraging the participation of citizens engaging them in contribution to public policies choices ranging from information to active participation for upholding the values of democracy.

This study is based on archival and qualitative data by the analysis and review of literature on the public sector investigating how new technologies help promoting democracy and participation connecting citizens with public administration.

The paper is structured as follows. Following the introduction, the role of information technology within public organization seeking sustainability is elucidated. In the second section, revitalizing democracy by information technology is elucidated. In the third section, after defining e-participation and elucidating different stages of e-participation, ICTs help to rediscover democracy and support participation as support to wealth of communities and source to reinforce citizenship, to support digital empowerment. Finally, discussion and conclusions follow.

The information and communication technology helps sustainable public organizations

Public organizations contribute to sustaining democratic life by maintaining public trust underlying democracy (Goodsell, 2006) and facilitate sustainable solutions (Bourgon, 2007). Public organizations should have to serve the public interest as result of dialogue with citizens based on shared values, leadership and respect for people developing policies through a process of effective collaboration with citizens as partners opening to learning and change by interacting with citizens (Denhardt & Denhardt, 2003; Denhardt & Denhardt, 2001; Vigoda, 2002; Bryer, 2006).

While e-government refers to use of information technology to improve the efficiency of government services provision to citizens (West, 2004), e-governance refers to the use of ICTs to support democratic processes, to improve interaction and relationships between government and citizenry fostering transparency, participation accountability (Dawes, 2008; Bannister & Connolly, 2012). Technology has made possible greater access to the policy process as result of dialogue and shared values by enhancing quality of citizens' participation (Denhardt & Denhardt, 2000). Investigating the concept of sustainability and analyzing how the information technology can help sustainability in government is an emerging theme (Fiorino, 2010; Janowski & Estevez, 2013; Larsson & Grönlund, 2014; Larsson & Grönlund, 2016).

Technology enables public organizations as open, responsive institutions that enforce democratic public values as impartiality, equity, honesty and fairness of government (Cordella & Bonina, 2012), serve the interest of citizens (La Porte, Demchak & Jong, 2002) and involve citizens in policy-making to restore public trust (Moon, 2002; Tolbert & Mossberger, 2006).

ICTs lead to new forms of governmental legitimacy and spaces of governance (Navarra & Cornford, 2012). ICTs contribute to providing citizen-centred services and access to information as public key resource of government (Brown, 2005) improving quality of services and fostering participation in democratic processes (Fang, 2002).

Revitalizing democracy by information technology

Technology helps democracy to evolve and involve people, organizations and public institutions to develop democratic mechanisms of governance and participation (Denhardt & Denhardt, 2003), leading to decentralized representative systems (Zittel,

2003), making accessible data and information about parliamentary institutions and legislative process, leading citizens to exert influence on policy making (Grönlund, 2001) to approach their parliamentarians before the vote (Milakovich, 2010).

Technology helps to enhance the quality of democratic governance by providing better information to citizens (Kakabadse, Kakabadse & Kouzmin, 2003). Technology opens access to information and enhances lateral communication among citizens leading to direct and strong democracy (Barber, 1999). The information technology is deployed to improve the effectiveness and efficiency of democracy that requires both a flow of information citizenry-government and effective citizen participation in the political process (Watson & Bundy, 2001).

Technology helps to develop democratic processes providing information for engaging in deliberation and participating in decision making (Tsagarousianou, 1999) enabling new forms of publicness within a public sphere (Tsagarousianou, 1998). Models of democracy in the information era tend to develop along a *continuum* in which the parliamentary chain of steering may play a critical part or new kinds of democratic practice are pointed (Bellamy, 1999).

E-democracy should contribute to sustaining dialogue and facilitating ongoing civic participation (Freeman & Quirke, 2013). E-democracy initiatives and projects may take different shapes confirming that technological and democratic linearity does not exist (Grönlund, 2003). ICTs serves as an easy way to reconcile the disconnection between people and governmental institutions and foster the public voice (Cavanaugh, 2000). ICTs help to improve the quality of information exchange government-citizens and strengthen participation by involving citizens in decision-making processes within deliberative and strong democracies in which citizens participate in the discussion about public affairs (Åstrom, 2001; Päivärinta & Sæbø, 2006).

Parliamentary institutions as symbols of political integration, representation and accountability (Raab & Bellamy, 2004) should embrace new technologies to reinvigorate representative democracy connecting to the public avoiding to become marginalized institutions that merely ratify what political executives or government parties decide (Bellamy, 2003).

The use of information technology can appear as illusionary in emphasizing the role of citizens as effective decision maker (Fuchs, 2009) and rhetorical to oppose civic engagement (Mahrer & Krimmer, 2005) coherently with a managerial model of interaction between government and citizens as customers (Chadwick & May, 2003) that helps to reinforce existing patterns of authority, influence (Rethemayer, 2006) and social structures (Parvez & Ahmed, 2006).

Sustaining e-participation: a definition

Political systems should contribute to sustaining democratization by improving participatory, deliberative and direct forms of democracy that help quality and equality of deliberation (Anttiroiko, 2003). The role of technology is to increase amounts of informal communication for sustaining the creation of social capital in communities as factor encouraging public participation (Komito, 2005).

E-democracy as the use of ICTs to support the democratic decision-making processes, relates to e-participation as knowledge, interactive and collaborative process. «Electronic participation, or eParticipation, is the use of ICT to facilitate political participation by enabling citizens to communicate with each other, civil society, their elected representatives and their government. Much more than government simply consulting citizens through surveys and petitions, eParticipation actively involves citizens in the policy process so that they can raise issues, modify agendas and change government initiatives» (Davies, 2015, p.19). According to Tambouris et al. (2015) e-participation can be defined as the participation using ICT as the only channel or alongside other non ICT channel, relating mainly to policy and decision-making for political or public policy purposes, as embedded in particular governance regimes, in the context of different political cultures, having direct impact and relations to policy goal and democracy.

It is important to consider different levels of e-participation and appreciate the value of e-participation as public policy and support for wealth of communities and means for sustaining citizenship and digital empowerment.

Understanding the levels of e-participation

Citizens can be better informed and included in decision making processes using technology that enable public participation to policy debates and consultation. Different levels of participation are elucidated in the literature about the use of ICTs for participation.

According to Macintosh (2004) three levels of participation are identified: e-enabling to support the access to the internet taking advantage of the large amount of information available; e-engaging as concerned with consulting a wide audience to enable contributions and support debate on policy issues; e-empowering to support active participation of citizens as producers of policy and facilitate bottom-up ideas emerging and exert influence on the political agenda and policy formulation. according to a growing scale over time in relation to OECD framework (2003) to take part in the decision-making and influence the policy agenda: *information* as a one-way relationship in which government make available information for citizens; in the *consultation* level citizens are encouraged to contribute their views on a particular issue; in the *active participation* citizens are empowered by actively participating in the policy making process (partnership).

Tambouris et al. (2015) identify five levels of participation between one-way or two-way channels: e-informing as prerequisite for citizens willing to contribute and e-involving as the one-way channel for providing information on policies ensuring that public concerns are considered; e-consulting and e-collaborating as a two-way channel for collecting public feedback, for a partnership with citizens actively participating in the developing alternatives and preferred solutions; e-empowering for implementing what citizens decide

ICT tools (ranging from web portals to consultation platforms, e-petitioning systems as examples) can be implemented to change or reinforce parliamentary institutions governed by path depth processes, support more participatory forms of citizenship and facilitate a two-way dialogue reinforcing participatory forms of citizenship and public

involvement based on a two way dialogue. Web portals help to bridge representation and communication functions. E-petitioning system are citizenship oriented and focus on interaction between citizens and public institutions like e-consultations (representation oriented) (Pratchett, 2007).

Towards e-participation as public policy and support for wealth of communities

E-participation initiatives should empower citizens for stimulating contribution to greater cohesiveness and inclusion within communities (Ahmed, 2007). ICTs support e-democracy and contribute to encouraging participation of citizens in policy making (Sæbø, Rose & Flak, 2008) facilitating a way of communication between citizens and politicians (Trechsel, Kies, Mendez & Schmitter, 2003).

Online citizen participation can enrich democratic processes and build public trust by enabling public agencies to receive broader and more diverse opinions from citizens than those available through traditional means of off-line participation. During the last decade within developed countries governments have developed policies to support e-participation initiatives to engage the citizen in decision-making processes in order to fight political apathy by increasing transparency and accountability.

New forms of electronic communication help to support democratic commitment of people that tend to rediscover public values and believe that participation of community will be related to government policies that encounter the will of people (King, 2006). The Internet provides a means of seeking the views of constituents on public policy and for improving the policy process. Internet-based petitions can be interpreted as a response to declining trust of citizen in political system (Lindner & Riehm, 2008).

Information technology offers citizens greater opportunities for to participate in decision-making processes at all levels because participation of citizens in political decision-making is considered a core aspect of modern democracy. Social sustainability relying on the widespread contribution of citizens in every area implies to develop models of democratic engagement and embed participation in the organizational and cultural infrastructures of modern governance systems. Thereby, public institutions should develop models of democratic engagement and embed in participation within organizational infrastructures of governance systems (Molinari, 2010), search the feedback of citizens about legislation or policies (Östling, 2011).

Sustaining citizenship and digital empowerment

E-democracy relies on the capacity of new communication environment to enhance degree and quality of public participation in government (Kakabadse, Kakabadse & Kouzmin, 2003). Participation serves important democratic values: legitimacy, justice and the effectiveness of public action (Fung, 2006).

Sustaining participation as pillar of representative democracy helps to contrast with some democratic deficits emerging in the last few decades: a growing apathy of citizens in front of the politics and democratic institutions; an increasing number of people turning away from politics and feeling unheard or abandoned by representative democracy and traditional intermediaries; declining voter turnouts; decreasing membership in political parties. In the Council Regulation (EU) No. 390, 14 April 2014

Establishing the 'Europe for Citizens' programme for the period 2014-2020 the European institutions should contribute to sustaining the European citizenship by improving conditions to ensure and strengthen civic and democratic participation and engagement by developing citizens' understanding of the EU policy making-process. Introducing ICTs can help to reinforce the European Union citizenship and enhance forms and tools for increasing civic engagement and citizens' participation in the democratic life and public affairs.

ICTs contribute to mobilising people from passive to active attitude, moving services from being 'user-centric' toward 'user-driven', and contribute to transform societal and political approach from 'government for people' into 'government by people'. Digital empowerment of citizens as paradigm of good governance relies on e-participation tools that lead the citizen to acquire digital skills to participate in public life.

ICTs do not ensure effective deliberative participation without engaging and including citizens in the political decision making (Rose & Sanford, 2007). There are no clear guidelines that direct and effectively contribute to implement a sustainable participatory process (Islam, 2008) even if ICTs contribute to increasing the effectiveness of e-participation initiatives (Phang & Kankanhalli, 2008).

Democratic institutions should provide sources for digital literacy and an equalized access to technology in order to include and drive people into political and democratic decision-making processes (Krueger, 2002; O'Donnell & Henriksen, 2002) searching for and effective and valuable citizen involvement and engagement an listened about their preferences on policymaking (Cardoso, Cunha & Nascimento, 2006).

Conclusions

Reinventing public administration for driving change relies on managing strategically the potential of new information and communication technology as a source that supports public organizations and people to rediscover democratic values and democracy as efficient and effective form of organizing public life that enables the creation of public value within communities. As institutions embracing and using information technology to make more transparent administrative processes, public organizations tend to search for effective involvement and participation of citizens and people to constructing the *res publica* as a driver of change and value creation within society.

ICTs offer public administration opportunities for connecting and reconciling with citizens by structuring new forms of democracy and enhancing the active participation of citizens as means and source to create public value within communities. New technologies drive public organizations to engage an aware and active citizenship for policy contribution.

The main contribution of this study is to provide an interpretive framework in order to identify the trajectories leading public organizations and citizens to move towards forms of participation that enable public value creation. Public institutions should use ICTs in order to revitalize democracy and enhance democratic values that emerge in effective and sustainable participation of citizens in policy making and in public life. Public institutions should support free access to data and information as public source

for enabling public value creation within communities. Public institutions should promote initiatives to remove the obstacles and barriers that impede to citizens to access the information as source that enables involvement and participation. Revitalizing democracy by use of ICTs relies on sustaining participation of citizens in policy choices and decision-making processes. Thereby, citizens should have access to information, have opinions, interact with institutional representative and government organizations within constitutional system. Citizens should be educated and trained to be involved in debate and discussion about public policies and problems that interest the community.

Building sustainable public organizations relies on involving and engaging people by embracing technology for rediscovering the values of democracy fostering the participation of citizens in public affairs and policy. Thereby, the design and implementation of e-participation initiatives seems to be still in its infancy. Public organizations strengthening the channels of two-way communication for active participation by embracing an approach based on citizen-centred collaboration have the opportunity to encourage and foster a participatory democracy technology-driven by linking forms of representative and direct democracy as to serve the legitimization function as necessary intermediaries opening up to contribution of citizens through co-production of social and democratic values.

Creating public value implies that public organizations are able to involve and engage citizens to access information, discuss and participate to policy processes and choices. Participation is emerging as a source and public value that enables communities to rediscover the meaning of people living together to have wealth and create public health. Technology helps participation as enabler of value creation processes. Sustaining participation by information technology helps public institutions, businesses and citizens to co-create public value. Participation tends to emerge as a source and driver of value creation within society. Future research perspectives imply to investigate how information technology helps participation within local governments and autonomies.

E-PARTICIPATION IN RUSSIA AT REGIONAL AND LOCAL LEVEL: VIEW OF THE GOVERNMENT OFFICIALS

Olga DEMUSHINA

*Russian Academy of National Economy and Public Administration
8 Gagarina St., 400131 Volgograd, Russian Federation
Olga-demushina@yandex.ru*

Abstract. *In recent years several e-participation projects have been introduced in some of the major Russian cities. However, there is a view that citizens in most other regions don't have as many opportunities to participate in decision-making processes. The purpose of this paper is to analyze the e-participation practices in regional and local government agencies in the Volgograd region in order to develop measures for improvement of the existing system. The study utilizes the following two methods: analysis of e-participation modes offered by regional and local governments and an expert survey. The survey was completed by 48 regional and local government officials responsible for information policy. The findings can be summarized as follows. All existing regional platforms provide opportunities to give feedback or ask questions related to the city's life. The local government website gives opportunities to participate in surveys that help to accumulate users' opinions and improve the quality of life in the city. On the other hand, the studied platforms do not provide collaborative tools (chat, shared agenda, forum, etc.). Their main aim is to give information, but not to involve citizens in decision-making processes. The experts evaluated the level of e-participation in the Volgograd region and identified the most important challenges. It has been concluded that citizens in the Volgograd region have fewer possibilities to participate in decision-making processes than citizens of the country in general. Among the variety of electronic services developed in Europe and the United States only a few (the least interactive as a rule) exist in Russia at the regional level. The most important problem highlighted by a majority of the experts (75%) is lack of clear and detailed e-participation strategy developed in the region. It has been reported that there is a need for developing this strategy at the regional and local level and citizens should be engaged in this discussion process. The other identified obstacles are the insufficient activity of citizens, lack of transparency in the local governments, and the complexity of e-services. Based on the investigations of this paper the following areas of improvement in this field can be proposed: development of an e-participation strategy in the region with citizen involvement in this process, enhancement of the existing e-participation services proposed by regional and local governments and adoption of new services, development of collaborative tools on existing platforms, simplification of e-services, using benefits of social advertising and social media.*

Keywords: *e-participation; e-services; local governments; e-democracy; public administration.*

Introduction

The main obstacles for the sustainable development of public administration in Russia are lack of transparency of authorities on the one hand and passivity of civil society on the other hand. The wide distribution of information technologies in the field of governance could solve these problems. The concept of e-democracy developed at the

end of the last century in the USA is widely spread nowadays in Russia as well. Federal and local e-government websites have been introduced and are working successfully. Nevertheless, e-democracy includes not only influence of authority on the society by means of information technologies, but also the feedback of the society, its reaction to government decisions and actions also by using electronic communications services.

Over the last 10 years, some government initiatives have been introduced by government bodies and agencies in Russia. There is a view that e-participation initiatives work successfully only in big cities such as Moscow and St. Petersburg whereas citizens of the most other regions do not have many opportunities to participate in decision-making processes.

The purpose of this paper is to analyze the e-participation practices in regional and local government agencies in one of the Russian regions and to develop measures for improvement of the existing system. The paper is structured as follows: Section 2 reviews the e-participation related literature, Section 3 presents the methodology, Section 4 analyses the empirical results obtained and Section 5 presents conclusion and recommendations for improvement in this field.

Literature review

Though the concept of e-participation has become quite popular in recent decades, there is still no single comprehensive definition of this term. It is difficult to understand what this concept includes, as each researcher either tries to create his or her own definition without a regard on the previous contribution or does not give any definition at all (Van Belle & Cupido, 2013). The explanation for this might be that this concept is broad and includes many kinds of activities: not only the most often considered e-voting, i.e., the use of electronic means to participate in the democratic electoral process (Macintosh, 2004), but also many other kinds of participation in governance at all levels: local, regional, national and international, i.e., planning, budgeting, decision-making implementation, evaluating (Grönlung, 2001; Sæbø, Rose, & Flak, 2010).

Based on theoretical consideration and earlier studies we can identify two views on the e-participation concept. Some schools consider e-participation to be a branch of e-government and the result of its development. They define e-participation as the use of electronic technologies for citizens to incorporate their concerns, needs, and values in government decision-making (Bennett, 2015; Bertot, Jaeger & McClure, 2008; Panopoulou, Tambouris & Tarabanis, 2010; Peristeras et al., 2009; Reddick & Norris, 2013). These studies view e-participation as a feedback of e-government, tools which enable communication and cooperation between citizens and public officials. A few researchers are skeptical towards this position and argue that it is not in accordance with some old e-government models. For instance, Layne and Lee's (2001) e-government model includes 4 stages: cataloging, transaction, vertical integration, and horizontal integration. As we can see there is no place for e-participation here.

With the aim to improve and develop the old concept a new e-government model has been developed. Bennett (2015) presents Siau and Long's model including 5 stages, where the fifth stage involves online tools such as e-voting, polling, and surveys to facilitate citizen participation. The authors call it e-democracy, but it also can be indicated as e-participation.

A number of contemporary studies broaden the concept and focus on a human factor in e-participation more than on its technological characteristics. They view e-participation as a way to engage citizens for the purpose to improve government activity and to strengthen representative democracy (Macintosh, 2004). Another aim is to improve communication between government agencies and citizens as well as among citizens themselves. Eccles and Kryus (2010) formulated the principles the connection between an entity and their stakeholders should be based on – collaboration and engagement.

It is in line with the concept of corporate dialog promoted by Bonson et al. (2012) which implies a fair equal relationship between all the participants of the communication process. We find it highly important for Russia where traditionally individuals are perceived as passive consumers of government services. The adoption of digital technologies in government can diminish the significance of the dichotomy of producer and audience (Hanssen, 2008) and increase the role of citizens.

One of the objectives of the study was to investigate and evaluate the e-participation modes and mechanisms offered by Volgograd regional and local governments. It should be noted that there are apparently not so many attempts in the contemporary literature to systematize electronic services and participation modes used by government agencies. The researchers usually concentrate on a few e-participation tools they intend to consider in their studies, but they do not try to summarize all the tools. For instance, Hanssen (2008) investigates and compares four e-participation forms in his research – e-mail, chat-groups, online-meetings, e-debates. Bonson et al. (2012) analyze utilization of technologies Web 2.0 and social media by municipalities. They summarize their data in the table according to their features and utility and demonstrate the newest e-participation tools: widgets, blogs, mashups, social networks etc. Anduiza, Gallego and Cantijoch (2010) investigate three modes of online-participation: contacting officials, donating money, signing petitions. However, the most authors focus on one or two tools and analyze its or their benefits and challenges for using. Van Belle and Cupido (2013) are concerned with using mobile phones as a platform to encourage public participation and engagement. A growing number of researchers from different countries regard examples of e-participatory budgeting adoption in local governance (Alfaro et al., 2010; Lironi, 2016; Matheus et al., 2010; Peixoto, 2009; Sampaio, Maia & Marques, 2011), participatory urban planning by digital tools (Rudd, Malone & Bartlett, 2017; Saad-Sulonen & Horelli, 2010; Wang et al., 2007), online participation in the legislative process (Coleman, 2004; Glencross, 2009; Lironi, 2016).

Based on the recent studies the following e-participation modes can be identified: submitting legislative initiatives; public consultations; evaluation of governments activities; e-budgeting; participatory urban planning; surveys and polls of citizens; e-voting; e-petitioning; e-referenda.

Most of these modes have been used to some extent in some of the Russian cities. Analysis of regional and local practices could be of a particular interest to compare and contrast the Russian experience with the situation in other countries. Therefore, this paper investigates finding and challenges of e-participation in Russia in view of the presented issues.

Methodology

Our strategy was a combination of qualitative and quantitative research. To achieve the main purpose this study utilizes the following methods.

1) Analysis of e-participation services proposed by regional and local governments. Data were collected by doing an analysis of the official websites of the Volgograd region local governments to obtain information about opportunities and channels they provide for citizens to participate online. The services were investigated according to the developed criteria: information related to the main aspects of city life, feedback, initiator of creation, timely updating, the simplicity of the graphic interface and navigation system, accessibility for citizens, possibilities to participate in decision-making processes through the sites.

2) The quantitative analysis was supplemented by a questionnaire expert survey [N=48]. This research tool is known for its sufficiently valid and reliable results and provides opportunities for researchers to study topics for which there is only scarce information (Hooghe et al., Bakker, 2010). A questionnaire was drafted to be filled by the experts. The survey was completed by 48 regional and local government officials responsible for information policy. The aim was to investigate their attitude towards citizen participation. The questions were selected based on the preliminary analysis of literature focused on e-participation practices in Russia and abroad.

The developed questionnaire consisted of four blocks: e-democracy situation in Russia and the Volgograd region, the most popular forms and sectors of e-participation, problems, and obstacles that might limit access to e-participation initiatives, actions of local governments to solve these problems. The respondents had the opportunity to complement their answers with written comments. To achieve the most reliable results the survey was conducted face-to-face. The meetings were organized during fall and winter 2017-2018.

Findings

E-participation tools on the regional and local government platforms of Volgograd

All e-participation platforms can be divided into two groups: initiated by governments and created by citizens. In Volgograd, only the examples of the first group can be found. In 2012 E-government of the Volgograd region was created with the ultimate aim to establish a united information space and infrastructure for successful communication between government and citizens. The objectives were also to facilitate transparency of government agencies and establish online liaison offices where every citizen could receive feedback from a local official. Thus, according to the plans, only two levels of e-participation were intended to be implemented: e-information and e-consultation. So, one of the important aspects of e-participation: e-decision-making (following the scheme developed by Macintosh, 2004) was left untouched while still in the planning stage.

According to the plans two platforms were established to implement the stated objectives: the official portal of regional government <http://www.volgnet.ru/> and the site of Volgograd city government <http://www.volgadmin.ru/>. The portal of regional

government provides links to the sites of local governments throughout the region. We present here the analysis of the platforms according to the developed criteria described in the previous section.

On both platforms, various kinds of information are available related to the main aspects of region life (education, health, social welfare, labor information, and environment). In addition, on a regular basis, government officials submit reports on the work they have done. The platforms have reference links to legislative texts, yet do not have any FAQ-pages.

Both platforms provide feedback opportunities to ask questions related to the region's or city's life. The website of the city government gives opportunities to participate in surveys that help to accumulate users' opinions and improve the quality of life in the city. Survey results are summarized in tables which are presented on the site.

As a general rule for any website, the navigation system should be simple to save users' time maximally. Both sites are updated on a regular basis, have good usability and a relatively clear navigation system. They offer a wide range of information which is well organized. But on the other hand, the platforms sometimes use complicated professional language and bureaucratic terminology which can limit access to the content for some participants. Besides, some tools require additional explanation for senior users which is not provided. Though the Volgograd region is considered to be multinational, access to government websites is possible only in one official national language. Special options for partially sighted persons are available on both platforms.

Social media enable the government to give people a large amount of useful information such as the location of offices or important events. Besides, social media are one of the ways to facilitate communication between government agencies and citizens due to available feedback tools. The official portal of Volgograd regional government has a social media presence on VKontakte (the most popular Russian social network), Facebook, Twitter, and Instagram. In most cases, they duplicate the information provided on the sites. Comments opportunities of the social media often remain unclaimed. Only a few posted citizens' comments have been ignored by local officials.

The analysis shows that the studied platforms do not provide collaborative tools (chat, shared agenda, forum, etc.). It can be concluded that their main aim is to give information, yet not to involve citizens in decision-making processes.

The results of the analysis are summarized in Table 1.

As we can see, in the Volgograd region only one level of e-participation has been implemented – e-information. Only two points “Information related to the main aspects of city life” and “Timely updating” have a maximum score. The analysis identified the chief problem: lack of possibilities to communicate with government officials and participate in decision-making processes. It is in line with conclusions made by American researchers about misbalance of functions performed by governments' websites which provide good information and deliver great services, but offer limited citizen-engagement opportunities (Zheng & Schlachter, 2018).

Table 1. Evaluation of the presented platforms (author's own elaboration)

Government platform	Information related to the main aspects of city life	Feedback	Initiator of creation (G or C)	Timely updating	Simplicity of the graphic interface and the navigation system	Accessibility	Possibility to participate in decision-making process	Social media presence
1	+++	+	G	+++	+	++	-	+
2	+++	+	G	+++	+	++	-	+

Evaluation of the e-participation experience by government officials

The second step of our research was to collect information covering experts' evaluating the current situation as well as their needs and expectations towards e-participation adoption at regional and local level. The survey target group were regional and local government officials responsible for information policy who agreed to participate in the survey. The survey was completed by 48 experts during the survey period.

The developed questionnaire consisted of the following blocks: e-democracy situation in the country and region, the most popular forms and sectors of e-participation, problems, and obstacles that might limit access to e-participation initiatives, proposals of local governments to solve these problems. The survey focused not only on statistical indicators of data but above all on the estimates and views of local officials on current situation related to e-participation opportunities in the Volgograd region. This sector is presenting an analysis of answers and inputs provided by survey respondents.

The aim of the first block was to indicate the most beneficial e-participation modes according to the respondents. Among the presented e-participation modes e-petitioning (52%) and surveys/polls of citizens (48%) were identified as the most useful. This is in accordance with current Russian studies marking high demand in these e-participation forms in Russia (Bershadskaya & Racheva, 2015; Chugunov & Bershadskaya, 2013; Demushina, 2016). Only a few experts chose such forms as submitting legislative initiatives (10%), evaluation of governments and officials' activities (7%), e-referenda (2%). None of the respondents marked e-voting, e-planning or e-budgeting. Total percentage exceeds 100% because up to three options could have been chosen. The results are summarized in Figure 1.

Figure 1. The most beneficial e-participation modes in the Volgograd region (%)
(author's own elaboration)

Respondents were asked to rate the effectiveness of e-participation practices existing in the country and region on a scale of 1 to 5, with 1 representing "very bad" and 5 representing "very good". 45% of the respondents gave 3 points to the e-participation practices both in the country and in the region. The rest evaluate the situation as "bad" or "very bad" (1 or 2 points). The results are presented in Figure 2.

Figure 2. The effectiveness of e-participation practices existing in the country and region
(author's own elaboration)

To evaluate e-participation progress at the national and regional level, the survey included questions about existing platforms and tools. The replies allow concluding that the Volgograd region has a significantly lower level of development in comparison to other Russian regions. The survey participants identified the following e-participation modes and mechanisms existing in Russia: information provision, surveys, and polls of citizens, crowdsourcing, public consultations, evaluation of governments' activities, e-petitioning, e-referenda. Among them, the only two - information provision as well as surveys and polls of citizens are in demand in the Volgograd region in the view of most respondents. In addition, the experts note that some of the popular e-participation forms in Europe have not been developed in Russia, for instance, e-voting, e-planning, and e-budgeting. Figure 3 shows that these forms have been chosen by the least number of the respondents.

Figure 3. E-participation modes and mechanisms in Russia and the Volgograd region (%)
(author's own elaboration)

Several barriers to providing e-participations have been identified by the respondents such as insufficient civic engagement, the complexity of electronic platforms and tools, lack of awareness of computers in general and of e-participation projects and tools in particular. The important problem highlighted by a majority of the experts (75%) is lack of clear and detailed e-participation strategy developed in the region. However, the officials admit that they share responsibility for the low level of e-participation development and mark insufficient transparency of governmental agencies as an important challenge.

The participants were asked about the reasons for insufficient civic engagement in Russia. All the replies can be divided into two groups: explaining it by the unwillingness of citizens to communicate with governments and by the inability of citizens to participate. The given replies are summarized in Table 2.

Table 2. Reasons for insufficient online civic engagement offered by the respondents
(author's own elaboration)

Unwillingness of citizens to communicate with governments	
1	lack of trust in government
2	lack of confidence in the possibility of change the situation
3	negative attitudes toward local officials
Inability of citizens to participate	
1	low level of computer literacy
2	lack of awareness of e-participation tools
3	Internet access problem and lack of infrastructure
4	lack of appropriate e-participation tools

Noting insufficient civic engagement, the experts do not endeavor to provide the citizens with an opportunity to be involved in building up e-participation strategy. 74% of the respondents argue that the initiative to develop e-participation in the region should be taken by government officials. 24% see non-governmental and public organizations in that role. Only 2% of the survey participants consider citizens to be responsible for issues regarding e-participation (see Figure 4).

Figure 4. Who should be the initiator of building up e-participation concept in the region? (author’s own elaboration)

Nevertheless, the respondents are positive about the involvement of the public in decision-making at regional and local level. 79% of the survey participants approve citizen engagement, 10% replied in the negative. Remaining respondents found difficulty in replying.

Several measures for involving citizens in communication with governments have been proposed by the officials: providing citizens with information about governments’ activities, invitations for public discussion, establishing public liaison offices, public reports of government officials, social advertising, social media (see Figure 5).

Figure 5. Measures for involving citizens in communication with governments (%) (author’s own elaboration)

Conclusions and implications

The purpose of this paper was to analyze the e-participation practices in regional and local government agencies in Russia. The findings of the study have both theoretical and practical implications. On the one hand, the study contributes through systematization of electronic services and participation modes used by government agencies. On the other hand, some recommendations for improvement of the existing system have been developed on the base of the conducted research, which can be used by regional and local government agencies to enhance the quality of public administration.

The analysis shows a lower level of e-participation development in the Volgograd region in comparison to other Russian regions and foreign countries. Most of the existing in the Volgograd region platforms do not provide collaborative tools. According to the analysis, their main aim is to give information, but not to involve citizens in the decision-making process.

The following barriers to providing e-participations have been identified by the respondents such as insufficient civic engagement, the complexity of electronic platforms and tools, lack of awareness of computers in general and of e-participation projects and tools in particular, lack of clear and detailed e-participation strategy developed in the region, insufficient transparency of government agencies.

On the base of the conducted analysis some areas of improvement in this field could be proposed: development of an e-participation strategy in the region with citizen involvement in this process, enhancement of the existing e-participation modes offered by regional and local governments and adoption of new services, development of collaborative tools on the platforms, simplification of e-services, using benefits of social advertising and social media.

Based on the conducted study, the following directions for further research can be proposed: to carry out a local population survey in order to find out the local citizens' opinions and attitudes towards the existing local e-participation services; to compare and contrast the Russian experience with the situation in other countries.

Acknowledgments: We thank the Russian Foundation for Basic Research for support, which enabled to prepare the presented paper (Project 16-13-34002 "E-participation: analysis of possibilities and development prospects in the Volgograd region").

Abstract. *The aim of this paper is to describe and analyze a best practice event organized and managed by the Italian Public Administration concerning the achievement of the UN's Sustainable Development Goals (SDGs). Specifically, we are going to answer the following research questions: RQ1, Which approach is the most appropriate for the management of highly complex events and inter-institutional projects?; RQ2, Which is the connection between 2030 Agenda and great events? Large-scale events, which are characterized by a dynamic complexity involving different national public administrations and institutional levels, require a special attention in selecting an adequate event management system. For this reason, after a detailed literature review on event management, this paper explores the concept of sustainable development and focuses on the traditional elements of social, environmental and economic pillars within the context of planned events. Given the objective of this work, the analysis of a best practice event will be useful to identify the main variables, in terms of sustainable strategic planning, execution and control, required to achieve the greatest level of efficiency in terms of cost optimization and quality of service delivery, also exhorting the Italian public sector to look for a structural renewal, to better use its available resources, as well as to foster a global sustainable growth. From this point of view, a relevant experience is the case of the Extraordinary Jubilee of Mercy, coordinated by the Prefect of Rome. Indeed, the latter, decided to adopt actions consistent with sustainability standards, thanks to the design of an inter-institutional network and the engagement of institutions at different levels. The Prefect of Rome achieved, in a very short term, three main results: coordination of the activities of the working groups (SDG 17); integration of internal and external surveillance and communication systems (SDG 9); collaboration with higher education institutions to acquire and disseminate knowledge (SDG 4). To systemize and combine the outcomes of these processes, as well as to analyze their consistency with sustainable development, the System Thinking technique was used.*

Keywords: *Event management; 2030 Agenda; Sustainable Development Goals; Sustainable events; Italian Public Administration*

Introduction

Events, especially the large-scale ones, produce several impacts on the territory, which cannot be exclusively related to an economic nature. The evaluation of the environmental and social effects (according to a triple bottom line approach) of an event is very complex, not only because the effects are often indirect and intangible, and

therefore difficult to be perceived and measured in time, but also because the variables which affect the outcomes are actually manifold. Moreover, because of the wide range of the goals pursued and of the heterogeneity of the subjects involved both directly and indirectly (stakeholders), it appears very difficult to single out the parameters according to which measure the success of an event. Several scholars, indeed, state that “the performances measures are different according to the subjects involved in the valuation (promoters, organizers, communities, sponsors, public...) and to the goals pursued” (Bowdin et al., 2011; Gartner & Lime, 2000; Richards & Palmer, 2010).

Consequently, the organizational efficiency needs to pivot on the specific competencies of the civil and ecclesiastical authorities. The visitors’ hospitality will result attentive, inclusive and relished inasmuch as the institutions will be able to work in synergy and harmony.

Interesting theoretical inputs can also be obtained from the analysis of the case study of the Extraordinary Jubilee of Mercy, co-designed and co-organized by two national governments (Italy and the Vatican State) and involving the Catholic Church “as a recognized universal international institution” (Meneguzzo, Fiorani & Frondizi, 2017). According to what has just been written, in the last Jubilee, a sort of “responsible cooperation” among the several stakeholders has been enacted, with the activation of bidirectional relations between all the involved subjects and of concrete steps in a long-term vision, keeping in mind what the event will leave to the territory, the so-called legacy (Allen et al., 2011).

This paper highlights some initiatives and operations carried out during the 2016 Jubilee of Mercy which might steer the sustainable growth of the City of Rome if implemented in the long run. To this aim, this analysis focuses on some of the Sustainable Development Goals which constitute the most ambitious challenge for the international community until 2030.

Our contribution starts from the analysis of this event, in which the authors have been directly involved as participants to the inter-institutional task force in charge of managing the event (led by the Technical Secretariat for the Jubilee). The paper is divided into three sections: the first one is dedicated to a thorough analysis of the existing literature on event management, with a focus on the sustainable theories of the planning, implementation, and evaluation of large-scale events. In the second section, the case of the Extraordinary Jubilee of Mercy is examined, with reference to the management and organizational decisions taken by the Italian institutions. In the end, section three presents a conclusive evaluation of the issue.

Theoretical event management framework

As Thomas et al. point out, event management “comprises the coordination of all of the tasks and activities necessary for the execution of an event regarding its strategy, planning, implementation and control” (Thomas, Hermes. & Loos, 2008). Starting from some pioneering studies (Getz, 1991; Hall, 1992), event management has been rapidly rising and recognized as a profession and a formal discipline, reflecting the “need within all societies for the professional management of events in the private, public and not-for-profit sectors” (Getz, 2005).

The first step to understand the meaning and scope of event management is the definition of the event itself. Etymologically, the term event derives from the Latin *eventus*, which directly translates as “occurrence, issue”. Today, events form an integral part of all societies (Ferdinand & Kitchin, 2012) and the recognition, by practitioners and researchers, of their role as an ‘industry’ has gained importance in recent times, also because of the quantitative and qualitative growth forecasts for their market (Thomas, Hermes & Loos, 2008). In the academic literature, many authors from different disciplines have discussed the meaning and definition of events and related concepts, failing to reach a unanimous consensus on standardized terms, definitions or categories.

According to Shone and Perry, an event is “that phenomenon arising from those non-routine occasions which have leisure, cultural, personal or organizational objectives set apart from the normal activity of daily life, whose purpose is to enlighten, celebrate, entertain or challenge the experience of a group of a people” (Shone & Parry, 2004). Getz defines events as “temporary occurrences, either planned or unplanned” (Getz, 1997). In order to emphasize the difference between unplanned and planned events, the term ‘event’ is preceded by the word ‘special’. A special event could be a “one-time or infrequently occurring event outside normal programs or activities of the sponsoring or organizing body”, as well as “an opportunity for a leisure, social or cultural experience outside the normal range of choices or beyond everyday experience” (Getz, 2005).

All the above definitions stress the unique and temporary nature of events, a feature also highlighted in the definition by Silvers, who considers an event as “the gathering of people at a specified time and place for the purpose of celebration, commemoration, communication, education, reunion and/or leisure” (Silvers, 2008).

Other authors, such as Jago and Shaw, focus on the tourism context, defining a special event as “a one-time or infrequently occurring event of limited duration that provides the consumer with a leisure and social opportunity beyond everyday experience”, often held “to raise the profile, image or awareness of a region” (Jago & Shaw, 1998).

Summarizing these definitions, we can define an event as a unique or infrequently occurring happening that occurs at a given place and time outside normal activities for individuals or groups of people.

Concerning typologies, events are often classified according to different criteria. In terms of size, it is possible to identify four different types of events (Bowdin et al., 2011; Jackson, 2013): local or community events, which are generally small and linked to a particular geography; major events, which attract significant numbers of visitors and media coverage; hallmark events, which are not automatically bigger than major events, but are synonymous with a particular place; mega-events, which are global and can influence the host country’s economy.

In terms of form, while Bowdin et al. identify only three types of events – cultural, sports and business events (Bowdin et al., 2001) – Getz (2005) distinguishes ten categories – cultural celebrations, religious events, political and state events, arts and entertainment, business and trade events, education and scientific events, sports events, recreational events, private events, events at the margin. Lastly, Raj and Musgrave (2009) differentiate between the following forms: religious events, cultural events, musical events, sporting events, personal and private events, political and governmental events,

commercial and business events, corporate events, special events, leisure events (Jackson, 2013).

Sustainable, effective, accountable and transparent events

In the evaluation of the impact of events, it is fundamental to keep into account, besides the immediate effects, also those arising in the medium-long term which, especially in the case of large-scale events, have a multi-dimensional impact, interesting many aspects of the life in the hosting community area. "Such events might even deeply and permanently affect the local welfare and lifestyle" (Mount & Leroux, 1994).

In recent times, the attention for the sustainability of the event has increased. By sustainable is defined "a development that satisfies the needs of the present without compromising the ability of future generations to satisfy their own needs" (World Commission on Environment and Development, 1987).

By approaching the event evaluation in terms of sustainability, it is necessary to examine different points of view: it is the case of the environmental, cultural, economic, political and social sustainability. Thus, "for an event to be sustainable, it should be part of a larger strategic project of cultural, social and economic development" (Richards & Palmer, 2010).

The capacity to organize and manage events based on the principle of sustainable development implies the existence of strong and cooperative institutions able to initiate inclusive, representative and reactive decision-making processes (target 16.7), involving all the stakeholders according to the "quintuple helix scheme" theorized by Carayannis and Campbell (2010). In this model, the government, businesses, universities and civil society cooperate toward the sustainable development, sharing of resources, instruments and especially, know how. The virtuous circles initiated by the cooperative approach stimulate, indeed, the crossed fertilization of sustainable ideas and projects (innovation) able to overcome the limitations of the "mental models" (knowledge mix, expertise, capacity) of the single subjects and of the limited resources available. In this way, large-scale events cannot be clustered within the boundaries of a single public administration or agency, but are characterized by a dynamic complexity that involves several offices and institutional levels (central/federal; regional; metropolitan/local). Moreover, in times of economic crisis and expenditure cuts, institutions arise as solid only when they manage to operate soundly in terms effectiveness, responsibility and transparency (target 16.6 "Develop effective, accountable and transparent institutions at all levels") but also with economy and efficiency.

For these reasons, it is important to examine, in the upcoming section, the Extraordinary Jubilee of Mercy, an example of best practice of the Italian public administration. The need for achieving extraordinary objectives with ordinary resources led the Prefect of Rome, through the Technical Secretariat for the Jubilee to single out modern, innovative, shared and long-lasting solutions for the management of the event, based on the synergies between all the subjects involved and in line with the SDGs (Fiorani & Di Gerio, 2016).

Case study: the Extraordinary Jubilee of Mercy

We are going to answer the following research questions:

RQ1. Which approach is the most appropriate for the management of highly complex events and inter-institutional projects?;

RQ2. Which is the connection between 2030 Agenda and great events?

In the Catholic tradition, the Jubilee is a major religious event which dates back to the XIV century with Pope Boniface VII. The 2016 Holy Year was defined “extraordinary” not only because it does not fall within the traditional 25-year timeframe, but also because it was the first “thematic” – dedicated to the Mercy – and “decentralized” Jubilee in the history of Christianity. With an unprecedented decision made by Pope Francis, the Holy Doors have opened also in the cathedrals and sanctuaries in all the Dioceses of the world, including 91 States and 560 Doors of Mercy. In line with this “globalist spirit”, the first Holy Door was opened in Bangui, Central African Republic, on the 29th November 2015. The Extraordinary Jubilee of Mercy, announced by Pope Francis on the 11th April 2015 and formally inaugurated on the 8th December 2015, ended on the 20th November. More than 21 million people arrived in Rome during 2016 from 36 different countries. Such an exceptional inflow of visitors and notable personalities determined important implications for the hospitality system in general, and for the mobility services, infrastructures, and national security.

As Morcellini (2016) said, “the Jubilee of Mercy set a milestone in Rome’s capacity to organize large-scale events, offering a very different image of the Capital from the one pictured by the media”. In this way, the strategic management of the event was assigned by the Italian and the Vatican State governments to the Prefect of Rome. The Prefect was in charge of defining the planning framework for managing the event and of ensuring that the whole information and communication systems worked. In view of these objectives, the Italian government (DPCM, the 4th September 2015) resorted to an innovative instrument: the Prefect of Rome was supported by the Technical Secretariat for the Jubilee (TSJ)¹⁴, a task force aimed at fostering the cooperation among the several local administrations and the integration of their operations. Under the management of the TSJ, the Prefect created eight thematic working groups, with the task of linking the different areas, and invited all interested institutions to participate (Figure 1).

All parties involved were proactive and accepted to share their resources, their information, and competencies: this led to the creation of a new concept of the large-scale event, which capitalizes on the synergies between all institutions involved, both at the intra-institutional and at the inter-institutional and inter-governmental levels, and between the eight working groups.

A thorough evaluation of the direct and indirect effects, both on the short and medium-long term, is an essential part in the reviewing phase of the event management. Similarly, the social and environmental impact needs to be assessed, in line with the UN Sustainable Development Goals.

¹⁴ The ‘Technical Secretariat for the Jubilee’ included 10 experts representing public administrations and territorial institutions (Ministry of the Interior, Lazio Region, Municipality of Rome), as well as delegates from Civil Protection, Carabinieri Corps and Fire Corps.

Figure 1. Inter-institutional synergies
(Di Gerio C., Fiorani G.)

The System Thinking map (Figure 2) shows some of the effects related to the Jubilee.

As Figure 2 shows, the partnerships (SDG 17, “Partnership for the goals”), i.e. the inter-institutional collaborations between public administrations, nonprofits institutions and enterprises, through the eight thematic working groups coordinated by the Technical Secretariat, together with the presence of strong institutions (SDG 16, “Peace, Justice and Strong Institutions”), are the key success factors of the last Jubilee.

The cooperation with university proved to be paramount (SDG 4, “Quality Education”). This goal, which underlines the link between primary education and professional training, was achieved through a memorandum of understanding between the Prefecture and the three State universities of Rome (La Sapienza, Tor Vergata, Roma Tre) which ensured a scientific and organizational support to the planning, management, communication, and post-event evaluation activities. In the “Third Mission” field, the three public universities contributed significantly to the success of the event, sharing their know-how and resources (teachers, recent graduates, spaces, and equipment) and offering to students the opportunity to serve an internship, with the aim to let them put into practice what they learned.

Figure 2. Multi-dimensional impacts: a sustainable Jubilee
(Di Gerio C., Fiorani G.)

Many technological (product and process) innovations (SDG 9, “Industry, innovation, and infrastructure”) realized during the Jubilee had a relevant positive impact on the responsible production and consumption models (SDG 12, “Responsible Consumption and Production”). A bright example is the inter-institutional centralized Jubilee Management Room (JMR), hosted by the System Room of the Rome Local Police forces, which played a major role in coordinating the Jubilee-related operations on the field, in monitoring the unfolding of events and assessing the different scenarios in real time. The JMR took advantage of an innovative shared cartographic system so to support the operations of all the Authorities watching the Jubilee events and flank the operation rooms of the single national and local police corps. Within the JMR, the creation of an integrated communication system based on TETRA radio allowed the numerous security forces on the field to share information through a single radio frequency. The JMR also had control on a comprehensive video-surveillance system based on the feed of the single local administrations with the aim to ensure a high degree of security for both the pilgrims and the local community. Thanks to the software and hardware sharing, the numerous entities involved through inter-institutional and public-private partnerships managed to rationalize their projects and intervention policies.

The JMR and the coordination activity of the Prefecture allowed to create public value and to initiate an “intelligent” management process, through a sound use of the resources available on the territory and constituting a best practice model to be applied to future complex events. It is noteworthy that the planning carried out by the TSJ during the Holy Year was characterized by a particular attention to maximizing savings and making the spending more efficient (SDG 12). The short timing (with an advanced notification coming just eight before the inauguration of the event) and the scarcity of financial resources demanded to resort to innovative solutions, including zero cost measures, considerable private capitals contributions, and the exploitation of the equipment already in possession of the national and local administrations.

This Jubilee was also modern, digital and built on a network basis. The 2016 Holy Year was, in fact, the first in the age of social networks, tablets, and smartphones, in the era of the continuous connection to the Internet. The Jubilee website and App provided information on monuments and churches, jubilee on foot itineraries, and mobility services. Communication was coordinated by the Italian institutions through the creation of a single website dedicated to the Jubilee called “Roma per il Giubileo” and a physical single Press Point from which all relevant information was conveyed.

The JMR and the single Press Point constituted the brightest examples of the integration of the several entities and administrations which, going beyond their identities and traditions, were called upon to joining their forces within a single operations room, under the same supervision and with a shared “Roma per il Giubileo” logo.

In order to explain more exhaustively the success of this large-scale religious event and the efforts made by the governmental institutions, it is noteworthy to address the link between the Jubilee and the other SDGs.

The interventions to make the City of Rome more inclusive, safe, flexible and sustainable during the event were manifold (SDG 11 “Sustainable Cities and Communities”). Concerning the mobility aspect, the public transport service was strengthened so to meet the high demand peaks in the celebration days and to guarantee the social and

environmental sustainability of the event. Moreover, thanks to a single direction of the mobility information¹⁵, it was possible to harmonize the messages about eventual service disruptions or delays and to convey urban and extra-urban mobility updates in case of necessity. The development of public transport made the City of Rome more sustainable in terms of the road system, emissions reduction, and livability. The positive environmental impact (SDG 13 “Climate Action”) of the Jubilee is also related to its global and widespread character, which minimized the movement of pilgrims allowing them to obtain the indulgence even in their own countries.

In order to crack down on illegal and unfair treatments to tourists and to raise the security perception of the Italian capital, Codacons, a network of associations for the consumer’s protection, realized a project called “Sportello del Pellegrino” aimed to provide legal assistance to pilgrims in more than 100 languages and fully managed by volunteers. Furthermore, several initiatives were achieved in favor of disabled pilgrims (SDG 10 “Reduced Inequalities”), in order to guarantee the righteous services. In this way, the App for urban mobility (Mapful) provided information on accessible routes for the disabled.

The Jubilee was the driver for the economic and employment growth in the City of Rome and its Province, in particular in the tertiary sector (SDG 8, “Decent Work and Economic Growth”). Nevertheless, the tourist inflow forecasted in 2015 was considerably reduced by the threat of ISIS terrorist attacks, the characterization of this event as a “widespread” Jubilee and the resort to unconventional staying options such as flat-sharing platforms and ecclesiastic structures.

Conclusions

The case study here analyzed shows that no one of the 17 2030 Agenda SGDs is feasible without the contribution of strong institutions. In this framework, the so-called quintuple helix cooperation, made up by governments, businesses, non-profit organizations, the civil society and the universities, emerged as paramount in order to ensure the success of the Jubilee.

Moreover, the issues of sustainable development are deeply rooted in an innovative, efficient, digital open and cooperative in public administrations. Based on this recent experience, the extraordinary spirit of sharing and cooperation which inspired the activity of all those involved in the success of the Jubilee of Mercy might constitute a valid example for all the future large-scale events in Italy and abroad. In fact, the challenge for great events is to think overdevelopment model in terms of sustainability and efficiency in favor of integration, cooperation, social innovation and ability to create inclusive networks; thus the engagement of several public actors is considered the rule rather than the exception.

In conclusion, the case of the Extraordinary Jubilee of Mercy, in our opinion, provides useful theoretical and empirical indications in the field of public management and governance and represents an important conceptual and operational challenge for the Italian public administration system. The integrated system for the management of the event, based on quintuple helix approach and integrated networks, could provide

¹⁵ Using ICT to support pilgrims and tourists’ mobility and transfer.

important indications for the future management of large events (sports, culture, promotion of the economy and the image of the country) and for the management of intervention policies facing environmental emergencies (such as recent earthquakes in Central Italy). This change of mind could be useful to turn a best practice into ordinary reality.

The other relevant aspect emerged from the paper concerns the introduction of a multidimensional assessment of the impact of the event. Short and medium-long term aspects should be taken into consideration, such as social and environmental impacts and legacy, in line with the United Nations' Sustainable Development Goals (SDGs). Goal 16 ("Peace, Justice and Strong Institutions") is definitely the one closer to a religious event like this and is the one which better meets the aims of the Jubilee: to promote pacific and inclusive communities and societies for the sustainable development. The extension of the event in the several countries (widespread Jubilee), the legal support provided by the Sportello del Pellegrino, the operations countering corruption and criminality, the public access to information, the promotion of initiatives to reduce inequalities, and the role played by the institutions for a representative, inclusive and reactive decision-making process are all examples of effectiveness, responsibility and transparency.

To conclude, we can answer the research questions stated.

For what concerns RQ1 (Which approach is the most appropriate for the management of highly complex events and inter-institutional projects?), the case of the Extraordinary Jubilee of Mercy highlights the need to work towards a co-operative approach, developing collaborative networks among interested actors. The aforementioned procedures of coordination and centralization of the operations constitute a novelty in the field of large-scale event management, with the TSJ as a highly innovative solution for avoiding flaws among the different entities involved in the organization of complex events. Ready-to-use technologies, the employment of available equipment and the interaction among public and private administrations were the key factors for delivering a high degree of efficiency and quality.

Concerning RQ2 (Which is the connection between 2030 Agenda and great events?), the integration of economic, environmental and social measures allows us to obtain a holistic view of the impacts generated by an event and, at least, its real level of sustainability. Such, material and immaterial legacy is added, considered as the starting point for the creation of a sustainable and smart city attentive to improving the quality of life of its citizens, businesses and institutions and the general well-being of the community.

Additional governmental efforts are required over the next 12 years in order to lead the world countries to the full implementation of the 2030 Agenda, also with respect to event management. The Italian government committed itself to this aim with resoluteness and resilience, as in the case of the Joint Italian-German-French Declaration on the US withdrawal from the Paris climate agreement, bearing in mind the outstanding results achieved in the organization of the Jubilee.

Abstract. *Public sector management reform driving strategic and organizational change within public administration is leading public organizations to rediscover the role of public office as vocation for developing effective and cultural changes driving behaviors of public employees. The aim of this study is to elucidate how promoting change within Italian public administration relies on public management reform driven by a 'laws and regulations perspective' that has influenced the processes of change and the design of work relationships within public employment. In Italy, public sector reform processes tend to follow a legalistic and juridical view to change leading to hybridization between traditional administrative culture and managerial culture. Public sector management reform following a legalistic perspective is leading to process of change in which new values drawn from managerial principles and administrative principles drawn by law-based tradition and legalistic culture tend to emerge and orient innovation and change. The study relies on the analysis of literature to understand the dynamics of change and reform within public sector with regards to public sector management reform and public employment reform in the Italian public sector. Reform supports the introduction of new behaviors and mentality within administrative culture of public employees and servants.*

Keywords: *human resources; public sector reform; change; law and public employment; public organizations.*

Introduction

As driving strategic and organizational change within public administration, public sector management reform is leading public organizations to rediscover the role of public office as vocation to develop effective and cultural innovation within behaviors and acts of public employees (du Gay, 1996). As institutions serving the public interest, public organizations should rediscover bureaucracy as form of organization that preserves ethic values, impartiality, equity and justice in governing the relationship between public bodies, citizens, businesses and no profit organizations (du Gay, 1996; du Gay, 2005). Rediscovering bureaucracy helps to rediscover the office as vocation and enhance the ethical attributes of good bureaucrat (du Gay, 1996; du Gay, 2005; Olsen, 2005).

The aim of this study is to elucidate how promoting change within Italian public administration relies on public management reform driven by following a *laws and*

regulations perspective that has influenced the process of change and the design of work relationships within public employment.

Sustainability of public organizations relies on driving public sector reform as a source for change by ensuring modernization and effectiveness of public administration, overcoming bureaucratic culture as the main obstacle to considering public administration as a community of people (public servant, citizens, organizations) that sustain efforts in order to promote innovation in public services delivery and quality in order to create social and public value.

In Italy, public sector reform processes tend to follow a legalistic and juridical view for change. The study relies on the analysis of literature on understanding change and reform within public sector and with regards to public sector management reform and public employment reform occurred in the Italian public sector since 1990. The analysis relies also on considering legislative innovation as source that enables processes of change and exerts influence on behaviors and culture of public servants.

Reform supports new behaviors and mentality but re-acknowledge the special nature of legal discipline on public employment and sector. It is possible to distinguish between the formal or legalistic side of reform and desired end or scope of administrative reform process evolving towards the change. Reform does not proceed and evolve towards an effective change of practices and administrative culture without people are willing and motivated to absorb new schemata and assume coherent behaviors (Capano, 1992).

Change is driven by behaviors, values and culture emerging in antithesis with previous paradigm and norms. Change may occur as new organizational behaviours experienced by people are introduced and implemented through explicit and tacit tasks (Dente & Lo Schiavo, 1999; Solari, 2007). Governing and managing change based on legalistic and juridical culture of public servants may fail in achieving results in terms of effective impact and consequences about public value creation (Rebora, 2012).

Creating public value relies on public managers sharing responsibility with other officials and citizens to decide what is valuable to produce with public resources by interacting with people to determine and organize the ends and means of service delivery and production (Moore, 1995).

Public institutions have to serve the public interest promoting effective collaboration with citizens as partners (Vigoda, 2002a; Vigoda, 2002b), encouraging shared responsibilities and public values (Bourgon, 2007), promoting the quality of human resources systems (Vigoda, 2000) driving public servants to engage in reciprocal communication with the public and helping citizens to meet their shared interests (Stivers, 1994; Denhardt & Denhardt, 2003).

The paper is structured as follows. After the introduction, in the second paragraph, understanding change within responsive public organizations is elucidated. In the third paragraph, reforming Italian public sector following the law-driven perspective for change is presented. In the fourth paragraph, a legislative view for governing and sustaining human resources by reforming public employment is presented. Finally, conclusions follow.

Understanding change within public organizations

In 1980s-1990s as theoretical and managerial response to inefficiency of traditional model of managing *res publica*, Npm doctrines have driven cultural and managerial change within public sector leading public organizations to import managerial practices from the private sector, focusing on re-organization of public bureaucracies disaggregated into agencies more flexible and output oriented, on financial efficiency and performance measurement, on separation of spheres between politics and management, reducing government functions through privatization (Hughes, 1994), stressing the private sector styles of management practices towards flexibility in hiring and rewards; a stress on greater parsimony and discipline in use of resources doing more with less, by cutting direct cost and resisting to union demands (Hood, 1991).

Thereby, the management state driven by public sector management reform has shown some limits, constraints and contradictory effects (Lane, 2009): neglect of meaning, no preservation of intangible values, unresponsiveness to requests and demands of citizens, democratic deficit within institutions. As stimulating competition mechanisms, public sector management reform driven by Npm doctrines have increased the chances of unethical behaviours associated with individualistic values reversing equity and legality as traditional values of public servants (Maesschalck, 2004). Npm doctrines contributed to deteriorate the corporate culture, the traditional work ethos and non-functional values, increasing a decline in motivation and work satisfaction, greater workload and stress (Diefenbach, 2009).

Governments should act to correct problems created by market dynamics and to maintain law, justice, individual rights, social organization, security and stability, and to promote prosperity for communities. Governments tend to protect public values as psychological and social constructs (Rainey, 2009). «Public values consist of outcomes based on what a government entity is supposed to be doing, and based on what citizens want it to do» (Rainey, 2009, p. 70).

Even if the interaction between public and private organizations is leading to a new public service ethos concerning honesty, community service and competition, consumer choice (Brereton & Temple, 1999), lawfulness, incorruptibility and impartiality tend to emerge as prevailing and specific values within context of public organizations (Van der Wal, De Graaf & Lasthuizen, 2008).

Reformers should take account of the value implications of reforms in order to correctly assess the ethical value and value consequences of public sector management reforms (Kernaghan, 2009). Achieving efficiency, efficacy and effectiveness does not comprise values and principles that inform the dynamics and life of public organizations. Innovation and traditional values of public service tend to coexist within public management reform. Public management reform should promote values as social equity, justice, fair treatment, inclusiveness and equity in compensation. Public management reform should support training and educational opportunities for sustaining human resource development, foster democratization and empowerment to improve citizen engagement and participative decision-making (Wise, 2002).

Reforming Italian public sector management: following a 'law and regulations driven' perspective

Reforming by laws and regulations helps to reinterpret the content of administrative reform driving change by following a bureaucratic paradigm rather than public management approach (Longo, 2003) without facing effectively the operational complexity and uncertainty of task and emphasizing the distance between formal organization (rhetoric) and reality (Adinolfi, 2004). Since public sector reform is to be codified in laws and regulations the legalistic nature of the political and administrative context may influence reform (Ongaro, 2010).

Since 1990 many public sector reform processes started in the Italian public administration. The Italian public sector reform introduced during the 1990s is part of an international trend (Npm) as global paradigm. Since 1992 the Italian public sector reform process has been implemented through a continuous flow of new legislation concerning: the reform of financial management and performance measurement; the reform of the civil service in terms of growing privatization of work relationships of public employees; the devolution of powers and tasks from the central government authorities to regional and local government autonomies. Public sector reform by law and regulations has driven performance management systems within Italian public administration (Panozzo, 2003).

Governing change and innovation within public administration relies on developing the quality of human resources as a source to enhance the autonomy of governing bodies (Rebora, 1991) and develop accountable public administrations (Valotti, 2000). Change within Italian public sector should transit through decrees and regulations view leading public administration to abandon bureaucratic approach and follow a public management performance-oriented perspective to drive learning processes and developing public employees as individuals motivated to public service and to assume new behaviors and attitudes (Rebora, 1999; Giannini & Bonti, 1997; Bonti, 2000).

The cultural variable is of essential importance to understand why administrative reform can vary in nature and follow very different paths (Capano, 2003). Introducing within public sector values, concepts and paradigm of Npm is exerting influence on the administrative culture (Pollit & Bouckaert, 2002). The prevalence of the administrative law paradigm influenced the process of change in countries with a legalistic culture or *Rechtsstaat* tradition driving the implementation of administrative reform merging the administrative tradition based on the respect of formal rules and the realization of the *public interest* as perspective coherent with an Anglo-Saxon system driven by New Public Management doctrines leading the Italian public system to orient behaviors of public servants and officials following a laws and regulations view (Pollitt & Bouckaert, 2000; Fedele & Ongaro, 2008; Panozzo, 2003).

Reforming public administration for change relies on sustaining the quality of human resources by proving a legal framework that enables public employee to rediscover public service motivation to serve the public interest and contribute to creating value within communities.

Reforming public employment: sustaining human resources

The nature of public service demands a sense of loyalty and attention to service on the part of public employees. Public organizations should support the employee work motivation and commitment public service rediscovering the organizational mission of public administration as service organization that creates public value with people (Wright, 2007). Public organizations should create an environment in which employees feel they can contribute both to the public goal and to an organization performing valuable services (Moynihan & Pandey, 2007).

People represent an important resource driving public administration to serve the public interest (Todres, 1994). The competitive advantage of organizations relies on sustaining the quality of human resources and on the capacity to manage people as human resources (Pfeffer, 1995). Human resources practices permit to improve and achieve high performances in public sector organizations and to communicate to employees the extent to which organizations trust employees (Gould-Williams, 2003).

Reinventing government relies on investing in human resources and professionalism of public employees in order to improve quality of public services for citizens and society (Crozier, 1988). Sustaining successful change within public organizations relies on providing resources in terms of training employees, developing new processes and reorganizing the structure, on employees able to learn new behaviours drawn by new policies or innovation in order to effectively institutionalize change in the institutional context (Fernandez & Rainey, 2006).

Reforming public employment: a legislative view for governing human resources¹

Traditionally, governance and management of work relationships within public administration implies to consider the need to maintain both protection of subordinate work and pay attention to the role played by public servant as acting for executive branch of public administration. In the public employment regulation, it is possible to distinguish the organic relationship that refers to the organizational relation between administrative office and the individual having the job in the public office and becoming an essential part of public administration and the service relationship that refers to the work or employment relationship between the individual as worker and employee and public administration as employer. In the Italian Constitution few rules govern the work in public administration: equality and prevision of competition-selection in access to public employment (articles 51 and 54); it is a mandatory duty for all the public employees to perform public functions by discipline and honor; penal, civil and administrative responsibilities of public employees (article 28); the design of internal organization of work units and departments within public administration in order to ensure impartiality and the *good way* (*buon andamento*) in the acting of public administration (article 97).

Preserving the constitutional principles that govern public administration system relies on ruling public employment by public and administrative laws and regulations as a means to ensure impartiality and the *good way* (*buon andamento*).

¹ Eufrasia Sena is the author of the paragraph.

Since the promulgation of law n. 93/1983 the collective bargaining in public employment tends to assume a relevant role with regards to rewards and compensation management, extraordinary work, professional training and personnel mobility coherently with constitutional and legal principles.

Reform driving change within public administration occurred in 1990s by introducing in the administrative law the principles of efficiency and efficacy and economic management as imported by private companies or organizations for profit.

Since 1990s the role of legislation is to drive change. The law n. 142/1990 concerning the reform of local governments and autonomies and the law n. 241/1990 governing the stages of administrative processes, the efficacy of administrative action and the separation between selection and implementation of political choices have opened to introducing new behaviors in the framework of public employment. The Decree n. 29/1993 introduced private work rules for public employment and attributed to the civil judge the competence in jurisdiction about the controversial between the employee and public administration. The civil judge is competent to evaluate trial regarding public employees. Previously, the administrative judge was absolutely competent for matters concerning controversial motives in public employment between the employee and public administration. Constitutional Court has blessed (sentences n. 313/1996 and n. 309/1997) the *Copernican devolution* occurred in public employment. Privatization of public employment does not obstacle but reinforces both the autonomy and the independence of public servants and officials in virtue of principles of impartiality and considering the *good way* (*buon andamento*) of managing *res publica* as a principle informing behaviors and action of public administration (Rusciano & Zoppoli, 1993).

Legislative innovation helps to consider the importance of work relationships between the individual as public employee and public administration as employer because it tends to stress the relevance of collective and individual bargaining as a source to restore the relationship between the individual and public administration as organization. The *Aran* (*Agenzia per la rappresentanza negoziale delle pubbliche amministrazioni*) as agency in charge of representing public administration in the collective bargaining and public employment unions having particular requisites of representativeness according to quantitative measurable parameters. To have access to collective bargaining in the public sector, only the unions that are mainly representative having a rate of representativeness not less than 5% considering both fees and the percentage of votes in the elections of personnel's representatives. As providing a link between public administration and *Aran*, the *sector committees* communicate to *Aran* the organizational needs of each work unit or department within public administration checking the coherency of the bargained document. Finally, the Court of Accountants checks formally and legally the agreement and the accounts verifying that the limits of expenditures are respected. The agreement is effective for all the public employees even if some of them do not adhere to any union because principles of equitable treatment are prevailing (Carinci, 2013).

Public management reform should contribute to redefining the relationship between political sphere and administrative sphere enhancing competence, autonomy and accountability as ethical values and principles that drive the culture of public employment. Only public management is in charge of directing the administrative action. Political bodies should be competent in defining the objectives and general

guidelines to orient behaviors of public servants and the action of public administration. Public management reform processes have followed a perspective oriented to cut the *connubium* between political sphere and administrative sphere in order to avoid blurred roles and tasks in the attempt to identify specific responsibilities, powers and duties that should allow to judge and evaluate strategic and operational choices of political and administrative bodies.

Law-driven reforms tend to follow a path of discontinuity than continuity following a contradictory and not always coherent logics. Public management reform processes were reinforced by the decree n. 165/2001 in which regulations on public employment were revisited and a new wave of laws and decrees (since 2009) contributed to qualifying public employment as a special matter to re-orient public employment towards the administrative law.

Recently, new rules for private employment were promulgated without any application to public employment. Some trends seem to be identified: centralization of selection procedures and planning; evaluating the merit coherently with new procedures to assess performance and contribution of employees; designing flexible forms of employment as the exception to the rule of full time employment and protection about the stability of job; special rules for public management.

The emerging and recent framework refers to a public servant who benefits of better law protections than private employees because the guiding principle that orient the vision and role of civil service is that better protection should ensure and enhance both the autonomy and the independence of public employee in terms of actions, behaviors and prerogatives. Thereby, today in the new scenario, acknowledging the autonomous and independent role of public employees implies control and evaluation and relies on designing mechanism of assessment to reward and/or sanction economically and financially the conducts based on merit and support productive behaviors coherently with goals and the ends of the public interest to serve citizens as users and beneficiaries of public administration outcomes (Zoppoli, 2018; Fiorillo, 2017; Giubboni & Colavita, 2016).

Conclusions

Reinventing public administration for change relies on managing strategically human resources rediscovering the role of public employees as drivers of strategic, organizational and cultural change and a source for design and implementation of public sector reform.

The aim of public sector management reform is to introduce and promote new and innovative behaviors, attitudes and procedures that involve public organizations to sustain the dialogue with citizens by ensuring high quality of public services and increasingly interact with citizens as people that play a relevant role as co-designers and co-producers of services they need and help the community to develop a path for growth and welfare over time by creating public value.

Reconstructing an organizational culture within public administration merging administrative tradition and managerial principles is an issue emerging from reform process and a challenge that public organizations and citizens have to face along a

continuum between rhetoric and reality using regulations and management principles as a source to improve public sector organizations to create and maintain social and public value.

Reform as a set of laws, regulations and decrees is leading the process of change in terms of new behaviors and values adopted by people managing techniques and interpreting laws. Change may proceed through people educated to values, beliefs and ideas coherently with enhancing the transparency as a value leading behaviors that effectively serve to restore the relationship of confidence with people as co-producers of public value by legitimizing behaviors, strategic and operational choices of public administration. Laws and regulations provide a platform that enables public employees and servants to develop behaviors coherent with a public service perspective that contributes to reinforcing the meaning of community where public organizations, businesses, citizens and other stakeholders interact in order to create public value.

Abstract. *Purpose - The purpose of this paper is to examine the scope and direction of the desirable changes in hospital management, as viewed by the directors. Design/methodology/approach - The study is based on a sample of directors of 125 Polish hospitals. The questions concerned indicating management areas which, according to the people in charge, required introducing changes. The subject of the research was to determine the extent as well as the scope of changes in the following management fields: the settling of accounts with the payer, revenue and costs control, the payroll system, the way of settling ward accounts, the sources of employee conflicts and the necessary staff training. Findings - The extent of change indicated in the 4 fields of change management (CM) did not depend significantly on the type of education received by respondents. The answers did not depend on work experience. It turned out, that uneven workload was the most common cause of conflicts in hospitals. The main problems are Interpersonal communication. There is a need to organize training, especially relating to interpersonal communication, professional training and quality. Originality/value - The article presents results of the research which would pertain to two key management fields: human resources, as well as financial resources.*

Keywords: *change management; hospitals; financial resources; human resources; organization development.*

Introduction

Change management (CM) is associated with the development of an organization (Burke & Noumair, 2015; Cummings & Worley, 2014; Hughes & Gosney, 2016; Worley & Feyerherm, 2003). There are also numerous findings concerning the impact of CM on employee behavior, displaying how various leadership styles in change processes affect ways of conduct (Neubert et al., 2008; Podsakoff et al., 1990; Avolio & Bass, 1995; Podsakoff et al., 1996). Nevertheless, there are no research results which would pertain to two key management fields: human, as well as financial resources.

CM (Carnall, 2018; Keen, 1981) is always a difficult task, even more so in the area of human health. Hospitals must therefore target all their efforts to improve the quality of the provided medical services and to achieve coordinated economic results. The accomplishment of both of these aims requires a deep insight into the organization and conducting economic analyses in order to evaluate the effectiveness of processes and the changes in HR policy. It is important to plan and determine the scope and direction of the changes in line with the proposed objectives. Still, these plans are subject to change due to either new legislative provisions or differing views held by the owners or managers. CM is thus a process affecting the development, structure and capabilities of an organization which acknowledges the altering needs of its customers (Moran & Brightman, 2001; Hayes, 2018). This is the reason why the identification of the needs of a medical facility's external customers (its patients), as well as its internal customers' (employees) needs becomes one of the key research areas in terms of constant changes which must be managed (Giebels et al., 2016). The concern for fulfilling the customers' needs remains within the remit of the managers. The directors are those who notice the needs the best, although meeting of certain demands is often restricted by legal regulation and the payer's and owner's interest. However, there are areas on which the supervisor's influence is bigger than on other. These include, among others: the payroll system, the settling of accounts in individual organizational units, the method of settling accounts with the payer, cost and revenue control, the organization of training, and conflicts. Accordingly, the purpose of this article was to identify the scope and direction of the desirable changes in hospital management as viewed by the directors.

Change management and organization development with reference to hospitals

Analyzing numerous definitions of organization development (OD) (Burke & Noumair, 2015; Burke, 1982), one can draw a conclusion that the development is targeted at solving the given organization's problems and its ability to cope with the changes occurring in its external and internal environment. The notions of CM and of organization development are closely related to one another. Their common ground is to achieve greater effectiveness through the introduction of changes. It is achieved through a planned shaping of processes with the use of behavioral science. The improvement in the overall efficiency of an organization occurs thanks to a reinforcement of the key organizational dimensions (including financial and human resources) with reference to its environment, mission, strategy, leadership, culture, structures, information systems, staff appraisal system and wage policy. Hospitals are the subjects which were (and still are) subject to many changes and which had to deal with these changes having limited budgetary resources. As a result of changing conditions arising from health service reforms, hospitals are faced with a considerable need for a rational use of financial and human resources. Since securing new sources of funding for the hospitals is hindered, it is reasonable for the hospital managers to focus their efforts on securing financial resources and developing human resources.

The development of an organization is also defined as a comprehensive process of data collection, diagnosing and formulating strategic activities, and carrying out interventions and evaluations. This bottom-up process is supposed to show the relation between strategy, organizational structure, processes, human resources and organizational culture, and is oriented towards changes in management. It is realized thanks to the cooperation and commitment of the members of a given organization (Beer, 1980). Sharing knowledge and experience among employees is a significant

element of the organization's development, which renders CM easier and more effective. CM is thus realized thanks to employees' skills and knowledge. It also concerns the process of learning (Cameron & Green, 2015; Todnem By, 2005). The functioning of an organization in complex conditions and uncertain environment is possible only when its education and training systems are open. This, in turn, results in achieving the previously set goals, solving problems, and positively affects employees' responsiveness to assigned tasks and the quality of their professional lives.

Although the notions of OD and CM have common objectives (such as the one mentioned by Warren and others, 1990), they differ with regard to the values towards which they are oriented. OD, often equated to striving for an increased value of human resources, is oriented towards the improvement of the human potential and its role within the organization, as well as delivering performance and gaining a competitive advantage. CM, on the other hand, is more focused on defining costs, quality and plans for action, all of which constitute a core value for clients and owners alike (Hayes, 2002; Paton & McCalman, 2000). A thorough overview of the researchers' standpoints regarding change management was presented by Rune Todnem By (Todnem By, 2005). CM comprises diverse variables analyzed from many different angles (Garud & Kumaraswamy, 2005). Furthermore, organizational changes are closely connected with the organization's strategy (Burnes, 2004; Rieley & Clarkson, 2001) and are triggered by various factors (Burnes, 2004; Luecke, 2003). CM may take place in the presence of conflicts among groups or individuals, thus constituting an impairment of interpersonal relations within an organization. The conflicts arise as a result of contradictory aims, a difference between interests or views, disputes and feuds. From the various kinds of conflicts (i.e. political, class, economic, social, ideological, cultural, or concerning values and goals the most frequent ones are connected with the division of labor and pay. They result from differences in financial and social standing, physical appearance and the standard of everyday life (Salejko-Szyszcak, 2011). In the face of the ongoing changes occurring within hospitals, the managers take measures to thoroughly investigate the areas which should be subject to change and which, at the same time, are linked to the efficient use of resources. The research literature lacks sufficient findings regarding change management in hospitals. Therefore, this study endeavored to fill this gap by presenting research results from the 125 surveyed hospitals.

Material and methods

In 2016 a survey research has been done investigating areas which, according to the people in charge of the facilities, ought to be subject to change in Polish hospitals. Directors of public and non-public hospitals were requested to fill in questionnaires sent in electronic form. 141 completed forms were received back, 16 of which had to be rejected due to missing answers. In the end, 125 properly filled in questionnaires were analyzed. The hospital directors were asked to indicate to what extent the following areas of the financial resources should be changed: the payroll system, the settling of accounts with the payer – the National Health Fund (NHF), and revenue and costs control. The need for change was rated on a five-point scale: 1 – no changes, 2 – a slight change, 3 – partial, 4 – a significant change, 5 – a general change. Moreover, the directors were requested to point out in the human resources sector the main causes of conflicts between employees, as well as the necessary staff training. There were 40 women (32%) and 85 men (68%) among the surveyed directors. Their work experience was as follows: 26 directors (20.8%) - less than 5 years, 40 directors (32%) - between 6-10 years, 59

directors (47.2%) - over 10 ten years of work experience. 47 of them (37.6%) received medical education, whereas 75 directors (62.4%) completed studies other than medical. The number and proportion of the given answers were calculated in a statistical analysis, while for the question concerning changes an average was also measured.

A two-way analysis of variance has also been done to check whether the opinions regarding the extent of changes needed in hospitals depended on sex, work experience, and the interaction between sex and work experience. Furthermore, a test for the significance of the difference between the means of two independent samples was run to examine if the type of education received (medical or not) influenced the viewpoint on the extent of necessary changes in hospitals. In addition, a χ^2 test of independence was applied to check whether the indicated conflict sources and needed training varied according to sex, work experience and the type of education received. A significance level of 0.05 was adopted.

Results - potential areas of change management in hospitals

Table 1 shows that, according to the surveyed, the way of settling accounts with the payer should undergo the biggest changes. 38.8% of the subjects marked that this activity should be changed in general. The payroll system ought to be altered significantly according to 30.04% respondents, altered partially in the opinion of 13.6% of the surveyed, and slightly changed according to 10.4% of the directors. Only 12.8% of the questioned deemed that the way of settling accounts with the NHF should be left unaltered. The surveyed hospital directors also pointed to the need of changing the payroll system. 5.6% of them stated that this system required introducing general changes, 17.6% claimed that significant, 51.2% - partial, 18.4% - that slight changes are needed. Only 7.2% of the respondents did not signal any need to change the remuneration system.

Table 1. Desirable changes in management according to the surveyed (in general)

What should be changed in the hospital				The payroll system	The way of settling ward accounts	The way of settling accounts with the NHF (contracts)	Revenue and costs control
The scope of changes	No changes	-1	n	9	18	16	24
			%	7.20	14.40	12.80	19.20
	Slight changes (2)		N	23	31	13	32
			%	18.40	24.80	10.40	25.60
	Partial changes (3)		N	64	41	17	42
			%	51.20	32.80	13.60	33.60
	Significant changes (4)		n	22	26	38	22
			%	17.60	20.80	30.40	17.60
	General changes (5)		n	7	9	41	5
			%	5.60	7.20	32.80	4.00

The total in each line N=125 respondents and 100%.

Accordingly, answers to the questions concerning the settling of ward accounts and controlling costs and revenues were similar. 7.2% of the directors stated that the way of account settlement should be completely changed; 4% thought the same about costs and revenues. 20.8% indicated a significant need to change the settling of ward accounts, while 17.6% marked a significant need to change the way of dealing with costs and revenues. One in three respondents noticed the necessity of partial changes in wards

(32.8) and of the control over costs and revenue (33.6%). Approximately a quarter of the surveyed declared a wish to slightly alter the account settlement (24.8%) and control of revenues and costs (25.6%). Meanwhile, respectively 14.4% and 19.2% of the directors replied that there is no need to change either the settling of accounts or the cost and revenue control. The extent of required changes in the four afore-mentioned areas is confirmed by the averages of the given answers. The highest scores received pertained to the way of settling accounts with the NHF (3.60), which means that majority of the respondents asserted that it requires partial or significant alterations. The payroll system requires less changes, with the average answer around 3 (rated as partial changes). In turn, the lowest averages obtained referred to the way of settling ward accounts (2.82) and the control over costs and revenues (2.62). The responses concerning the four areas of CM did not depend significantly on the type of education received by the directors (medical or not) (Table 2). However, the extent of changes indicated in the two fields, the remuneration system and the way of settling accounts with the NHF, depended largely on the sex of the surveyed directors (Table 3 and Figure 1).

Table 2. Desirable changes in management in hospital according to the type of education received (average answers given)

Changes in the hospital	Education		Statistical significance	
	medical	non-medical	t	p
The payroll system	3.15	2.85	1.765	0.080
The way of settling ward accounts	2.87	2.78	0.428	0.669
The way of settling accounts with the NHF (contracts)	3.81	3.47	1.321	0.189
Revenue and costs control	2.53	2.67	-0.659	0.511

Table 3. Desirable changes in management in hospital according to the type of education received (average answers given)

Changes in the hospital	Work experience (WE)	Sex		Total	Statistical significance
		Female	Male		
The payroll system	up to 5 years	4.00	2.58	2.96	Sex F=9.425; p=0.003 WE F=1.739; p=0.180 Sex*WE F=4.456; p=0.014
	6-10 years	3.26	2.95	3.10	
	over 10 years	2.86	2.87	2.86

Figure 1. Desirable changes in hospital according to work experience and sex (average answers)

On average, women indicated a greater need for change in these sectors than men (in case of the payroll system 3.25 vs. 2.82; in case of accounts 3.88 vs. 3.47). Furthermore, the replies concerning the extent of change did not vary significantly with regard to the hospital directors' job seniority. Nevertheless, there appears to be a substantial influence of the interaction between sex and work experience on the opinion concerning two of the CM areas: the payroll system and the way of settling ward accounts. Women with work experience under 5 years showed a significantly larger need for changing the remuneration system (with an average rate of 4) in comparison with men with equal job seniority (on average 2.58). The answers given by female and male employees with work experience of more than 5 years fluctuated around 3, which means that according to them the system ought to be changed partially. Similar relations were exhibited in answers referring to the need for changes in ward account settlement. Women with work experience of less than 5 years displayed a greater wish for changes in ward accounting (an average of 3.86 - meaning a significant need) than men with the same job seniority (on average 2.86). In turn, the average reply given by directors with work experience above 5 years when asked about the need for changes in settling ward accounts was lower (ranging from 2.56 to 3.24), which means that in their opinion this field requires changes, but to a lesser extent.

The study of conflicts in hospitals as a factor of change

The survey research also required the respondents to indicate the sources of conflicts (Table 4 and Figure 2). Uneven workload emerged as the most frequent cause of

conflicts, with more than half of the surveyed directors (55.2%) pointing to this answer. The next most frequently indicated reason of conflicts were problems concerning interpersonal communication (according to nearly half of the questioned (48%)). One third of the respondents claimed that the disproportions in salaries were also a source of disagreement. The following causes of conflict were enumerated at similar rates: additional allowances (24%), differences in education (23.2%), and higher material status (20.8%). Only 8% of the questioned hospital directors did not observe any conflicts. A significantly larger percent of women (60%) than men (42%) pointed to communication problems as a source of conflicts. On the other hand, a smaller number of women (12.5%) than men (43.5%) claimed that conflicts arise as a result of disproportions in salaries. Moreover, a substantially higher percent of the respondents with work experience between 6 and 10 years signaled that the material status is a cause of conflicts. The remaining answers regarding the sources of conflicts in hospitals did not depend largely on sex nor work experience, while none of the replies depended significantly on the type of education received by the directors.

Training as a change factor in the light of research

The directors recognize the need to organize training, especially concerning interpersonal communication (81.6% of the surveyed), professional training (77.6%), and quality (68.8%), which is presented in Table 5 and Figure 1. A less common indication regarded the need for additional training in: cost accounting (36,8%), CM (28,8%), labor law (25.6%), and information management (23.2%). The least frequently indicated needs for training referred to management psychology, finance management, infrastructure management, marketing, and human resource management (less than 15%). Female directors less frequently (55%) than male directors (73.3%) pointed to the need of training regarding quality, at the same time more frequently indicating the necessity to organize CM training (40% of women vs. 23.5% of men) and information management training (35% of women vs. 17.65% of men). When it comes to CM, a significantly smaller number of employees with work experience under 5 years (8%) than those working between 6 and 10 years (40%) or above 10 years (30.5%) acknowledged the need for training in this field. The directors who received non-medical education pointed to the need for marketing training more frequently (13%) than those with medical education (2%). The remaining replies concerning training did not vary significantly according to sex, work experience and the type of education obtained.

Conclusions and discussions

The presented research results constitute an identification of the scope of changes which will undoubtedly be introduced in the surveyed hospitals. It turned out that the payroll system ought to be modified. Moreover, it appears that also the management of resources should be subject to a thorough analysis. This concerns the unsatisfactory manner of settling accounts with the NHF and of the wards in particular. It is the obligation of the managers to improve the quality and efficiency of the work environment. The identification of the conflict sources may positively contribute to the implementation of changes in human resources management. It has been established that the most common causes of conflicts indicated by the respondents are not a major problem, since (provided they are willing to do that) the employees may easily eliminate them by themselves. Poor interpersonal communication also emerged as a significant cause of conflicts. A positive aspect of this is the fact that directors have substantial knowledge concerning the irregularities within the organization and that, accordingly, the indication of these irregularities enables the introduction of proper changes in certain areas, thus eliminating the conflicts. As far as other sources of conflicts are concerned, uneven workload was mentioned as the greatest cause, followed by problems with communication and disproportions in salaries. From these, it seems possible to eliminate the two former sources, for they do not depend on any external factors. Unequal access to training and conferences was not a significant cause of conflicts, although it has to be noted that taking part in training may also eliminate certain communication problems.

Therefore, it lies within the competence of the manager to thoroughly analyze the financial activities on which he or she has influence. All the fields of CM presented in Table 1 may undoubtedly be changed. The biggest problem concerns the ways and regulations concerning the settling of accounts with the NHF. However, the directors do not have much power and influence when it comes to solving this issue. What they can do is to make sure that the accounting procedures are thorough and sound. Furthermore, the study showed that the payroll system, as well as cost and revenue control system, ought to be altered. The change management in Polish hospitals should unquestionably be supported by a previously conducted detailed examination of the areas subject to change. Although the research results are a reflection of the directors'

outlook, their measures they take cannot remain isolated. CM ought to take place with the participation of employees and ought to take into consideration their different views, ideas and standpoints (Michalczyk, 2014). This, however, calls for further research.

While analyzing organizational changes in the Polish health service it must be highlighted that they were not performed in an unforeseeable way, since they were planned beforehand. The changes encompassed the following fields: strategy, structure and organization, techniques and people. The implementation of strategy is connected with a constant analysis of changes occurring in all areas of hospital activity, whether social or economic, in accordance with the law and international regulations. CM is also performed with due regard to the analysis of the competitors' behavior, the suppliers, the patients, and other parties concerned. This, in turn, leads to organizational changes which involve the given organization's resources. In the case of human resources, it is necessary to support employees by enabling them to improve their qualifications through training, by taking care of the working environment, by eliminating conflicts and by motivating them to work more efficiently. In the case of material resources, changes refer to a more effective use of assets and the selling of redundant assets. These can be implemented in any area of the hospital's activity, but they require an earlier recognition of the reasons behind such changes (Kister, 2015a, Kister, 2015b). What is more, the organizational transformations were undertaken primarily as forms of restructuring operations (Wysokińska – Senkus A., Senkus P., 2013). The transformations have influence on, inter alia, the ways of settling accounts between wards, as well as human resources management, including the planning of forms of employment, the training system, and solving conflicts. The rules concerning efficient application of changes which, in turn, are accountable for lowering the risk of venture failures have been thoroughly described in literature (Penc, 2007) and ought to become a basis for their implementation (Nadler & Tushman, 1989).

Abstract. *The following paper was prepared as the result of the cooperation and development programs that have been run by the authors and Joseph Ayo Babalola University and is the voice in discussion to encourage Nigerian Government to develop strong and effective agriculture sector. Modern-day Nigeria has emerged as Africa's largest economy, with 2014 GDP at over 568 billion USD (The World Bank, 2016). Thanks to the largest population in Africa and the strongest economy Nigeria is often referred to as the "Giant of Africa". Although oil has been playing the mayor role in the structure of Nigeria's GDP the economic growth for over the last five years has been driven by growth in agriculture, telecommunications, and services. Economic growth and stability makes Nigeria according to PwC "one of the potential power economies of the world" (PwC 2016), but one the country is still facing several challenges economic, social and environmental. The biggest challenge is that according to the The World Factbook strong economic growth have not translated into a significant decline in poverty levels (Central Intelligence Agency, 2016). The government and President has announced plans to increase transparency, diversify the economy away from oil, improve fiscal management and working to develop stronger public-private partnerships for roads, agriculture, and power. That actions and activities are very positive, but because of significant differences between for example Europe, North America and Africa they should be designed specifically for Nigeria. The actions and activities should be strategically planed and follow latest developments of management and technological revolution like sustainability, knowledge sharing, Internet of things. The paper presents the challenges and possible scenario for Nigerian agriculture, one of the most dynamic and important sector for Nigerian economy, that produces not only economic output but could be nowadays fundament for welfare society supporting it with food, jobs and place to live.*

Keywords: agriculture; internet society; knowledge management; knowledge sharing; business; sustainability; cradle 2 cradle.

Introduction

According to Barak “Entrepreneurship creates new jobs and new businesses, new ways to deliver basic services, new ways of seeing the world—it’s the spark of prosperity.” The experts see the opportunities to develop SMEs in high-growth sectors like agribusiness, ICT, and clean technology (The World Bank, 2016).

Nigeria is a democratic country which operates the presidential system of government that has gained the independence on 1 October 1960. There are 774 local governments, 36 states and the Federal Capital Territory. The GDP of Nigeria has been constantly growing until 2014 to the level of 568 Billion of USD, but in 2015 has started to fall. The main cause of this “slowdown” of GDP output is because the Nigerian economy is tightly-coupled to “commodity prices” in the international markets especially oil.

The challenge as ben noticed by Nigerian government that has proposed several plans to drive economic growth, attract investment and diversify the economy with more focus on the non-oil sectors including agriculture, mining, manufacturing and services (PwC, 2016).

Figure 1. The key figures for Nigeria
(Source: Adeola Falodun, Doing business in Nigeria, 2016

<http://www.slideshare.net/AdeolaFalodun/doing-business-in-nigeria-with-a-focus-on-the-fashion-industry> access 2018.08)

Current population in Nigeria has exceeded 180 million of people that makes 2,4% of the world population, ranking the 7th place. Nigeria's population increased by 57 million from 1990 to 2008, a 60% growth rate in less than two decades (IEA, 2008). It is the most populous country in Africa. The Nigerian population pyramid, age population structure has very favorable structure according to social sciences, unlike Poland, Europe or developed countries (Figure 2).

Figure 2. The population pyramids Nigeria, Africa, Europe and Poland 2017
(Source: <http://populationpyramid.net/> access 2018.08)

Such structure is also another challenge for Nigeria and with other economic factors it determines some key aspects to take under consideration when developing plans to for Nigerian growth:

- Nigeria has totally different number of young people than Europe or developed countries (about 40% of the population is under 14, while in the European population is going older and older);
- Because of demographics, less young people, less hands to work, the priorities for European countries are mainly related to ensuring the economic growth and wellbeing that requires less active jobs. That is why the significant investments in agriculture's technology, manufacturing and services has been made there;
- The very strong investment in technology also is very good idea for Nigeria, but crying to copy industrial model would not solve the problem of poverty and unemployment. Only the implementation of the sustainable model with fundamentals on small and medium enterprises in the manufacturing and services sector and family farms based on private property, could result in economic self-sufficiency for Nigerian families because it creates jobs and gives food;
- Building economic growth on big corporations founded by foreign investments could result in corporate (neo)colonialism because for foreign investments only profit counts, rather than ecological and social situation like income distribution inequality, "Land Grabbing" and ecological disaster (Michalski, 2014).
- Building economic growth on big corporations founded by state remains big economic experiment that was conducted in XX century especially in Central

and Eastern Europe and the USSR. In general, the experiment has result in significant drop in economics and productivity, society degradation.

The effects of inadequate development policy are very tragic and affects all economy of the country society and natural environment so should be planted with care and respect. The example of large scale economic growth policy failure for very big area is the case of “Aral Sea”, where irresponsible management of water resources used for agriculture, irrigation of big cotton plantations has caused drying of one of the biggest sweet water reservoir in the World and ecological and social disaster. The Nigeria with is demography and economical potential is entering new age of possible welling but the Nigerian politicians and economics have to draw their unique scenario because the economic ideas and practices base only on the dictation of high productivity and high profit without care of society and ecology had bankrupted with the 2008+ Global Economic Crisis.

The priority for the decision maker should be to support economically self-sufficient Nigerian family that in business either manufacturing or services sector could result is small or medium family based enterprise that gives stability and employment. The potential of the Nigerian agriculture sector seems to be nowadays even bigger than the rest economy. That sector also faces bigger challenges than the rest of economy, that is why the rest of the paper is devoted to highlight the challenges and try to point he adequate solution in order to build well developed Nigerian society.

The side effect of the pointed practices could also help to overcome the national Nigerian problems like:

- National identity problem and Tribalism;
- Poverty, Unemployment and Inequality;
- Corruption, Home violence, Terrorism and High level of child mortality;
- Poor education.

The facts about Nigerian agriculture

The total agricultural area, according to FAOSTAT, 72 million hectares, that is about 77% of total country area. Arable land is 35 million hectares, that makes less than 48% of agricultural area.

Figure 3. Agriculture statistics and agriculture land in Nigeria
 (*10 000 ha or 10 sq.km) (Source: own work, based on FAOSTAT, 2016)

Total agriculture production of crops was estimated to be 152 million tones. The main 10 crops planted in Nigeria are Cassava - 54 831 600 tones, Yams - 45 004 340 tones, Maize - 10 790 600 tones, Oil, palm fruit - 7 968 440 tones, Sorghum - 6 741 100 tones, Rice, paddy - 6 734 000 tones, Sweet potatoes - 3 478 270 tones, Groundnuts, with shell - 3 413 100 tones, Taro (cocoyam) - 3 273 000 tones, Cow peas, dry - 2 137 900 tones. That 10 planted crops make over 94% of total crops production in Nigeria (figure 4).

Conclusions could be retrieved from the analysis of yields of the main crops planted in Nigeria:

- Cassava – the yield in Nigeria 70 323 hg/ha, the best yields of that crop India – 349 594 hg/ha, the average yields of Cassava in the world was 112 121 hg/ha. That means that the growth of yields in Nigeria has still great potential because the achieved yields there are only 20% of the best yields achieved in the world and 62% of the average;
- Yams – the yield in Nigeria 70 001 hg/ha, the best yields of that crop Ethiopia – 279 805 hg/ha, the average yields of Yams in the world was 92 015 hg/ha. That means that the growth of yields in Nigeria has still great potential also in case of that crop, because the achieved yields there are only 25% of the best yields achieved in the world and 76% of the average.
- Maize – the yield in Nigeria 14 616 hg/ha, the best yields of that crop United Arab Emirates – 367 619 hg/ha, the average yields of Maize in the world was 47 217 hg/ha. That means that the growth of yields in Nigeria has still great potential also in case of that crop, because the achieved yields there are only 3% of the best yields achieved in the world and 30% of the average.
- Oil, palm fruit – the yield in Nigeria 26 667 hg/ha, the best yields of that crop Guatemala – 227 692 hg/ha, the average yields of Oil, palm fruit in the world was 117 416 hg/ha. That means that the growth of yields in Nigeria has still great potential also in case of that crop, because the achieved yields there are only 11% of the best yields achieved in the world and 22% of the average.
- Sorghum – the yield in Nigeria 9 727 hg/ha, the best yields of that crop United Arab Emirates – 241 358 hg/ha, the average yields of Sorghum in the world was 26 000 hg/ha. That means that the growth of yields in Nigeria has still great potential also in case of that crop, because the achieved yields there are only 4% of the best yields achieved in the world and 37% of the average.

Figure 4. The structure of crops and meat production in Nigeria
(Source: own work, based on FAOSTAT, 2017)

The situation described above could be generally seen according to any kind of crops planted. There are differences because of climate in the certain countries but still when one benchmarks the Nigerian agriculture with the countries with similar climate one should get similar findings. That factor is important in case of drawing the scenarios for Nigeria.

When considering meat and main animal products production the total production achieved in 2014 about 1,4 million tones (figure 4), 650000 tons of hen eggs and 570 000 tons of milk. The analysis made on crops production and meat and main animal products production shows that agriculture is very extensive.

Interesting findings one could made when analyzing agriculture products international trade of Nigeria and OPEC oil prices (figure 5).

Figure 5. Value of Nigerian export and Import and OPEC oil prices
(Source: own work, based on FAOSTAT, 2017)

The Nigerian economy, as the country is forth OPEC exporter is strongly depended on oil prices, co the form about 1995 then the oil prices had started to grow also the agriculture products trade deficit had grown. During that more or less 20 years of prosperity on the oil market Nigeria had financed their agriculture trade deficit with income from oil export. The dangerous situation has appeared in 2015 when oil price has significantly dropped. Nigeria has not totally been prepared for that situation. Moreover, the situation on the oil market, and also prices, will never be the same again also because of the growing popularity of substitute to oil energy sources like for example shell gas or all palette of the renewable energy sources like wind, sun, etc. That situation draws the new challenges in front of Nigerian economy and agriculture

The new challenges in front of Nigerian economy and agriculture

In management before drawing any plans for the future there is significant need to get as much information as one can about past, current situation ant the trends that could affect the plans, not only according to one issue that is currently researched but also the issues closely related to it. Especially the things that has to be carefully examined are changes.

Charles Robert Darwin has told "It is not the strongest species that survive, nor the most intelligent, but the ones most responsive to change." (Senkus, 2013. p.57), in case of Nigeria that means that the only condition for success in developing the economy is to adjust to new trends either economic or ecological or social. Jack Welsh, the former CEO

GE, told “if you do not change you’re dead”, the symptoms of economic troubles for all oil-dependent countries could be noticed with oil price drop that is why they would have to find the way to change in order not to get bankrupted. But the hardest thing still comes ... Albert Einstein has told “We can't solve problems by using the same kind of thinking we used when we created them”. That are words are very actual nowadays. Probably no conventional way to encourage the economic growth would work. It would not work, because external environment has totally changed especially according to technology, knowledge sharing or information flow. So how to draw right plans and chose the good actions? Let us begin from general to specific.

The ability to answer the question is bigger when one understands the “game-changers” or often called the technological waves. The theory of waves has been developed by Alvin and Heidi Toffler. They claim the entire history of mankind is considered by them within the context of three consecutive but simultaneously interpenetrating one another technological waves:

- the agrarian - began about 10,000 years ago and was a consequence of the spread of inventions and skills related to farming that resulted in forcing the settled way of life. The wave has not gone yet. The wave is still present in the countries where the most of the society is depended on agriculture. It does not mean that that countries are worse than others, it only means that in order to achieve success another plans have to be drawn and another actions have to be taken. According to agriculture to make it modern and efficient, the new technologies like Internet of Things, new way of planting or breeding or new platforms, based on Internet, to educate farmers and share the knowledge have to be implemented;
- the industrial - began with the invention of movable type by Johannes Gensfleisch zur Laden zum Gutenberg about 1450 and this wave was surged thanks to James Watt, who improved the atmospheric steam engine in 1763, which was constructed by Thomas Newcomen. However, the invention of a steam engine and launching the industrial era are assigned to James Watt. This wave revolutionized steel production methods, popularized electricity and brought new means of transport and mass communication as well as it popularized standardization and uniformity. Like in case of the agrarian wave that wave has not been over. That wave is characteristic for the countries with strong industry, but without R&D centers. The interesting thing about the theory is that the countries on their way to development do not necessary need to get into all waves. It is only necessary to uncover and implement the new trends that are shaping industry of the future like 3D printing (it allows to manufacture goods directly in the place where they are needed);
- the information - is directly related to the emergence of new technologies enabling unlimited communication amongst people. It is characterized by the development of different services and leaving mass production; it is not a talk about simple services here such as gastronomy or hairdressing, since they cannot, according to Toffler, become the icons of the third wave. The services associated with the third wave are above all the services related to creation and accumulation of knowledge and modern technologies; the third wave is still in the initial phase and faces the resistance of the defenders of the second wave (Toffler, 1997).
- Nigeria and the rest of the world is now at the end of the third wave or even at the beginning so the “proven programs” that were conducted in the other countries would not work the for Nigeria. The easiest way to improve agriculture would be

to use more fertilizers, more heavy machinery and promote monoculture ... such action runs in a straight line to repeat the environmental, economic and social catastrophe of the “Aral Sea”.

Table 1. Gaps in the Nigerian demand and supply across key crops and activities (2016 estimate) (Source: Federal Ministry of Agriculture & Rural Development in the document “The Agriculture Promotion Policy (2016 – 2020) - Building on the Successes of the ATA, Closing Key Gaps”)

Crop	Demand	Supply	Gap (%)	Observations
	(million tons)			
Rice	6.3	2.3	173,9	Insufficient supply chain integration remains issue
Wheat	4.7	0.06	7 733,3	Driven by demand for various types of wheat (white, hard, durum), etc. for bread, biscuits and semovita
Maize/Corn	7.5	7.0	7,1	Limited imports required but can shift due to feed demand
Soya Beans	0.75	0.6	25,0	Animal feed and protein cost alt. driving demand
Chickens	200 birds	140	42,9	Gap filled by illegal imports that enter market at lower price point than domestic producers; gap also a moving target based on fast food/QSR demand
Fish	2.7	0.8	237,5	Fall off in ocean catch and weakness in aquaculture yields due to cost of fish feed a constraint on growth
Milk / Dairy	2.0	0.6	233,3	Driven by insufficient milking cows and low yields (~15-25 liters/day versus norm of 35 - 40 liters NZ/US)
Tomato	2.2	0.8	175,0	Actual production is 1.5 million tons but 0.7M ton is lost post-harvest
Yams	39	37	5,4	Limited gap today but volumes expected to rise in planning period
Oil Palm	8.0	4.5	77,8	Refers to fresh fruit bunch (FFB) from which oil is extracted at a 10% - 15% efficiency rate
Cocoa	3.6	0.25	1 340,0	Demand is global demand which will rise to 4.5M by 2020
Cotton	0.7	0.2	250,0	Demand is for seed cotton and could rise to 1.0 - 1.5 million tons subject to textile sector revival
Sorghum	7.0	6.2	12,9	Demand will rise further as use in feed grows in 2016 - 2020. Import of malt extracts and glucose syrup is currently used to manage gap, hence a commercial threat for Nigerian farmers

Federal Ministry of Agriculture & Rural Development in the document “The Agriculture Promotion Policy (2016 – 2020) - Building on the Successes of the ATA, Closing Key Gaps” has identified the gaps in Nigeria demand and supply across key crops and activities that are presented in table 1.

The figures shown in the table 1 show that Nigeria has a lot to do but the chance for the success is great because even the gap in the production of strategic crops is from about 5 to 7 733% the average value is 793,4 and the modal value is 174,5%. Getting back to the yields analysis one could notice that even when to improve yields about 200% the

yields still remain relatively low to worlds average. The select challenges and production gaps by value chain stage were displayed (table 2). The most important when restructuring Nigerian agriculture is to treat agriculture as the part of the all Nigerian economy system, not stand as alone.

Table 2. Gaps in the Nigeria demand and supply across key crops and activities (2016 estimate) (Source: Federal Ministry of Agriculture & Rural Development in the document "The Agriculture Promotion Policy (2016 – 2020) - Building on the Successes of the ATA, Closing Key Gaps")

Area	Illustrative shortcomings
Input Supply	- GES's limited focus and exit strategy set aside, with material implications for Ministry's budget, hence the sharp rise in indebtedness to banks. The system has many leakages from farmer registration and data capture to supply and distribution mechanism. - Insufficient access to improved variety seeds e.g. still a 300,000MT gap between demand and supply of seeds
Financing	- Credit access particularly for small holders remains weak - Nirsal's 2013 change in credit guarantee rules disrupted market for agriculture financing until mid-2015 when rules were reviewed again - Backlog of unpaid GES loans (estimated at N39B) has slowed down bank lending - Of ~\$8 billion in domestic and foreign investor commitments often cited, only limited volumes actually moved from idea to reality
Infrastructure & Logistics	- Investment inflows into infrastructure and midstream logistics e.g. warehouses, storage, processing systems remains rudimentary - Staple crop processing zone (SCPZ) strategy has not yield results. For example, Kogi SCPZ has not taken off due to withdrawal of Cargill, the anchor investor from the project
Production	Growth in food production remains limited due to gaps in input supplies e.g. rice; hence rice imports still exceed \$1 billion/annum. Outlined below is an <i>illustrative</i> "best estimates¹" of demand-supply gaps given data quality issues still present in Nigeria. It is anticipated that as production gaps are closed via yield improvements, per/ton equivalent costs will also decline, helping reduce food costs and ultimately, inflation.
Market Access	- Post-harvest losses still an issue but improving moderately - Illegal food imports remain an issue, depriving farmers of market opportunities
Others	- Federal - State coordination of policy became significant challenge; some states made choices at odds with federal approach e.g. continuing direct procurement of fertilizer - Absence of program delivery infrastructure / unit at the federal and state levels; held back key implementation and donor funding - Data collection and evidence based reporting remains weak, hence tracking results / M&E continues to be a challenge

¹ Based on data drawn from FMARD, NBS, NIRSAL, CNBC Africa, commercial bank project analysis, FAO, USDA GAIN. NDPI Foundation, and private estimates

One of the most interesting of management that is e part of “sustainability trend” is Cradle to Cradle. The application of the model has been already conducted in Ford Motor Company, Deso and many other industries and agriculture (Bouma et al., 2011; Docuyan, 2011). Cradle to Cradle (C2C) is a biomimetic approach to the design of products and systems. It models human industry on nature's processes viewing materials as nutrients circulating in healthy, safe metabolisms. It suggests that industry must protect and enrich ecosystems and nature's biological metabolism while also maintaining a safe, productive technical metabolism for the high-quality use and circulation of organic and technical nutrients (McDonough & Braungart, 2010; Hunter, 2008).

Figure 6. The idea of Cradle to Cradle (C2C) and Model C2C
(Source: McDonough & Braungart, 2010; Cradle to Cradle Products Innovation Institute, <http://www.c2ccertified.org/>, dostep 2013)

According to the "Cradle to Cradle" model (figure 6), all materials used in production or services, such as metals, fibers, dyes, fall into one of two cycles: "technical metabolism" or "organic metabolism":

- The technical – is strictly limited to non-toxic, non-hazardous synthetic materials that have no negative impact on the environment and also can be used in continuous cycles, without loss of integrity and quality. Thus, these materials may be used in a continuous cycle, instead of being "recycled", where part of the product, becomes waste;
- The biological - contains materials that once used, can be thrown in any environment and decompose in the soil, providing food for small life forms without affecting the environment.

The main principles of Cradle to Cradle (C2C) are:

1. Waste = Food is a basic concept of organic waste materials becoming food for bugs, insects and other small forms of life who can feed on it, decompose it and return it to the natural environment which we then indirectly use for food ourselves;
2. Use current solar income – the designers of the method encourage to renewable sources of energy for example powered by sun;
3. Celebrate diversity – that means biodiversity, cultural diversity or conceptual diversity.

*Figure 7. The principles of Cradle to Cradle (C2C)
(Source: McDonough & Braungart, 2010.)*

Nigerian Government and the agencies, universities and specialists who would do the agriculture or other branches of Nigerian Economy reorganization in order to achieve success have to treat their job as project or portfolio of projects and run them under project management regime and except of sustainability, use new management tools and techniques like business process management, lean management.

The scenario for Nigerian agriculture development

Federal Ministry of Agriculture & Rural Development of Nigeria has prepared also the development policy with the certain fundaments:

- Food security;
- Import substitution;
- Job creation;
- Economic diversification.

From the perspective of sustainability and new management trends the policy is well prepared because the policy seems to be treated as system.

Figure 8. Agriculture Promotion Policy Fundamentals

(Source: Federal Ministry of Agriculture & Rural Development in the document (2016) "The Agriculture Promotion Policy (2016 – 2020) - Building on the Successes of the ATA, Closing Key Gaps").

The ministry has also described some priorities (Federal Ministry of Agriculture & Rural Development 2016) but based on experience of the countries like Poland or other countries who has gone through economic transformation some comments and additions should be made. The priorities are mentioned below in points and are commented based on practical and research experience of the authors:

- 1) Agriculture as a business - focusing the policy instruments on a government-enabled, private sector-led engagement as the main growth driver of the sector. This essential principle was established in the ATA and will remain a cardinal design principle of Nigeria's agriculture policies going forward. Comment: The introducing "agriculture as a business" is great idea because actually managing the agriculture farm does not really differ from managing any other business. Peter Drucker told "management is divided only into good or bad management". The thing that has to be mentioned is structure of farms and structure of capital:
 - a. Farm structure – large farms are more effective and more profitable, but definitely do not create jobs. The high effective big farm in Europe or US employ 2-3 workers on each 100 ha while the large state farms in communist times in Poland employed about 12 workers. Unfortunately, Polish government did not care to much about that numbers that has result in very high unemployment in the rural areas. The most effective farm type for Nigeria would be, based on the polish experience, would be family farm.
 - b. Capital structure – the policy makers in Nigeria has to take care also for proper balance between foreign and domestic capital. The foreign capital is welcomed, but no controlling it could result in neocolonialism because foreign capital would invest only in big profitable farms and transfer the profits to their countries. Such mechanism is unfortunately noticeable in Polish banking sector, where 98% of banks are foreign and industry sector where almost none of big companies are Polish. The significant thing is that one who owns the capital decides how many people to employ and how much to pay for the job. That means that in order to company would be high profitable the wages have to remain low. The other way to build very economically effective society is the Japan way described in the Imai Masaaki book "Kaizen: The key to Japan's competitive success" (Masaaki 1986).
- 2) Agriculture as key to long-term economic growth and security - focusing policy instruments to ensure that the commercialization of agriculture includes technologies, financial services, inputs supply chains, and market linkages that directly engage rural poor farmers because rural economic growth will play a

critical role in the country's successful job creation, economic diversity, improved security and sustainable economic growth. Comment:

- 3) Food as a human right – focusing the policy instruments for agricultural development on the social responsibility of government with respect to food security, social security and equity in the Nigerian society; and compelling the government to recognize, protect and fulfill the irreducible minimum degree of freedom of the people from hunger and malnutrition.
- 4) Value chain approach – focusing the policy instruments for enterprise development across successive stages of the commodity value chains for the development of crop, livestock and fisheries sub-sectors, namely input supply, production, storage, processing/utilization, marketing and consumption. Building complex linkages between value chain stages will be an important part of the ecosystem that will drive sustained prosperity for all Nigerians.
- 5) Prioritizing crops – focusing policy on achieving improved domestic food security and boosting export earnings requires a measure of prioritization. Therefore, for domestic crops, the initial focus in 2016 – 2018 will be expanding the production of rice, wheat, maize, soya beans and tomatoes. For export crops, the initial focus will be on cocoa, cassava, oil palm, sesame and gum Arabic. In 2018 onwards, the export focus will add on bananas, avocado, mango, fish and cashew nuts. Investments in closing infrastructure gaps to accelerate productivity and investment in these crops will also be sequenced to reflect capital availability and management attention.
- 6) Market orientation – focusing policy instruments on stimulating agricultural production on a sustainable basis, and stimulating supply and demand for agricultural produce by facilitating linkages between producers and off takers, while stabilizing prices or reducing price volatility for agricultural produce through market-led price stabilization mechanisms (commodity exchanges, negotiated off-take agreements, extended farm-gate price under value chains coordination mechanisms, agricultural insurance, etc.)
- 7) Factoring Climate change and Environmental sustainability – focusing policy instruments on the sustainability of the use of natural resources (land and soil, water and ecosystems) with the future generation in mind while increasing agricultural production, marketing and other human activities in the agricultural sector.
- 8) Participation and inclusiveness – focusing instruments on measures to maximize the full participation of stakeholders including farmer's associations, cooperatives and other groups, as well as NGOs, CBOs, CSOs, development partners and the private sector. This places a premium on the role of these organizations or groups as agents of economic change in general and agricultural economy in particular, thereby drawing benefits from their policy advocacy roles as partners to and watchdog of government.
- 9) Policy integrity – focusing policy instruments on measures for sanitizing the business environment for agriculture, in terms of accountability, transparency and due process of law, ensuring efficient allocation and use of public funding and fighting corruption on all programs involving public resources. This also applies to compliance with international commitments, protocols and conventions that Nigeria is a signatory to. To make real integrated policy and actions the specific frameworks and tools are needed like Business Process Management or Project Management. The implementation of the frameworks and tools could ensure that could ensure transparency, eliminate corruption and finish project with success (Senkus 2013),

- 10) Nutrition sensitive agriculture – focusing policy instruments on addressing the issues of stunting, wasting, underweight and other manifestations of hunger and malnutrition with particular reference to the vulnerable groups, which include children under 5, nursing mothers and persons with chronic illness and disabilities.
- 11) Agriculture's Linkages with Other Sectors – focusing policy instruments on the connected relationship between agriculture and other sectors at federal and state levels, particularly industry, environment, power, energy, works and water sectors.

According to authors the scenario drawn for Nigeria by the Federal Ministry of Agriculture & Rural Development, with could make the success of the Nigerian agriculture development. Moreover, investing in agriculture even when the world is at the end of the third technological wave still could be profitable for the country. The example or that thesis is Denmark. Generally, two thirds of the Danish agricultural production are exported to more than 100 countries all over the world. Only half of the export goes to the EU-countries. This means that Danish farmers are competing with farmers on the world market (Danish Agriculture & Food Council). The significant thing is that Danish agriculture is based on family farms and co-cooperatives.

Another thing should be also included in the scenario of developing Nigerian agriculture and Nigerian economy at all. The thing is Internet and the related to it like Internet of Things (IoT). IoT could dramatically change the business reality in agriculture that could effect in: significant drop of the production costs, better risk management, better decision making and incense of the welfare in the rural areas (Senkus, Łuczak & Skrzypek, 2014). The only thing is to do by Nigerian government is to set up Internet backbone network as a framework for knowledge sharing.

Conclusion

Nigeria is standing now in the front of very big challenge related building their economic security through to reorganizing the agriculture sector but in order to achieve success the three main activities should be undertaken.

- Developing the family farm model to make them food self-sufficient,
- Developing the co-cooperative model for proper quality of agriculture supply,
- Building the broadband Internet infrastructure to spread specific knowledge.

Abstract. *The topical character of the given paper in the positive effects of the interbudget relations working model is presupposed by the dependence management of financial stability in the Russian industrial cities, caused by transfers from the higher level budgets and bringing about the lack of motives to create favorable conditions for business structures functioning, for enlarging their own tax basis of territorial formations. Aim: working out and finding foundations for a complex methodological approach to the estimation of interbudget relations national model effectiveness as a trend to enhance the tax potential of Russian industrial cities. Using the instruments of the correlation analysis, the character and trend of relations between the scope of interbudget transfers' different types and the figures of the integral indicator of an industrial plant are explained. The method of average figures is applied in the process of the norms optimal figures calculation for interbudget transfers, which condition the maximal increment of the integral indicator, characterizing the tax potential of the territorial formation and the balance of all the state government levels and the tax-payers' economic interests. The paper expounds the results of exploring and finding grounds for the principally new complex methodological approach to estimation of the national model effectiveness in interbudget relations through comparing the criteria of "interbudget transfers" and "the integral indicator of tax potential", introduced by the authors. Its systematized mathematical algorithm is represented. The expediency of the introduced criteria practical application and of the represented mathematical algorithm are investigated in the estimation of the*

financial providing leveling positive effects with state instruments on the example of major industrial cities of the Ural Federal District. The carried out research contributes to the development of ideas about the interbudget regulation on the basis of all levels of power and economic subjects' interest's coordination by means of stimulating the process of tax potential boosting. The results of using the complex methodological approach to estimating the interbudget relations model organization effectiveness through comparing the criteria "interbudget transfers" and "the integral indicator of tax potential" are of objective character and can be used by different countries' financial-budgetary bodies of management in the process of: forming the offers to correct the mechanism, distributing transfers, aiming at stimulating the social-economic development of territorial formations; regular monitoring of asymmetry in the budgetary environment and the correspondence of results in territorial financial policy factual indicators to optimal figures.

Keywords: budget; subsidies; tax revenues; tax potential; non-tax incomes; subventions; interbudget transfers.

Introduction

The modern economic situation in the industrial cities of the Russian Federation is characterized by the chronic lack of their own resources to cover the expenses of the local budget. The state applies the instruments of horizontal and vertical leveling in financial providing of the territories and orients on the distribution of revenue powers among the Russian Federation, the subjects of the Russian Federation and municipal organizations, which leads to the high level of revenues centralization in the federal budget and, accordingly, to negative effects. The negative effects of the national budgetary practice are the resource dependence on the higher level, the decrease of interest on the part of the government bodies in industrial cities to the expanding of their own revenue basis, as well as the arising temptation to increase the amount of expenditures and the deficit of local budgets. It is noteworthy that "many fiscally decentralized economies rely heavily on transfers from upper to lower-level governments as well as on equalizing transfers between lower-level governments" (Lundqvist, 2015, p.43). That is why the increase and solidifying of an industrial city tax potential requires, first of all, working out and practical application of the stimulating mechanisms, instigating modern territories to try to enhance the total resource basis.

Founding grounds for the topical character of the research subject-matter, it seems appropriate in Table 1 to depict the content of interbudget relations traditional models, presupposing the specifics of not only the revenue sources distribution but also of municipal territories.

Comparing the traditional models of interbudget relations organization, it seems expedient to note that the system of state-used instruments of territorial financial providing leveling changes depending on the condition of outer and inner social-economic environment, its historical and political-legal specifics. With this, "the budgetary federalism model effectiveness becomes maximal only as a result of a long-term step by step agreement of interests between the society and the state, on the one hand, and the federation, territorial communities and the local population, on the other" (Wildavsky, 2004, p.157).

Table 1. Review of interbudget relations traditional models' contents (Composed by the authors)

Name of the model	Specifics of the model	States, using the model
German model	The model is aimed at the decrease of horizontal disproportions in the level of financial providing and realized using redistribution of tax sums, first of all, from the interest rate tax and providing the substantial amount of interbudget transfers. The system of interbudget leveling presupposes the existing taxes, the sums of which are distributed among all the levels of the budgetary system, their partial redistribution to cover the gaps in the territorial financial providing rate.	Germany
Anglo-Saxon model	The Anglo-Saxon model of interbudget relations is characterized by decentralization of the budgetary system – the municipal organizations have a substantial level of independence, affording them to introduce additional and double taxes. The system of interbudget leveling presupposes the active use of purpose grants.	The USA, Great Britain, Canada, India, etc.
The unitary model of interbudget relations	The unitary model of interbudget relations is characterized by the decrease of the territorial financial providing level disproportions through transfers, defined as the difference between the basic financial needs and the basic financial revenues, which, by no means, are related to the factual replenishing of the local budgets.	Japan, Sweden, Denmark, etc.

Recognizing the importance of foreign experience in the organization of interbudget relations, its copying in the conditions of the Russian Federation is impossible and fruitless, because:

- first, there are significant differences in the self-organization of some state regions potential;
- second, the system of national budgetary management is based on the principles of self-government and subsidiaries, which presupposes the basic role of municipal bodies in satisfying the social needs;
- third, the level of territorial financial stability is traditionally characterized by significant horizontal and vertical disproportions, requiring certain amounts of financial resources for their decrease.

No doubt, the stated problem is perceived and discussed at different government levels. Though, in our opinion, this problem cannot be solved positively without the complex research of the national model of interbudget relations as the trend to enhance the Russian Federation industrial cities tax potential as the instrument to coordinate economic interests of all the government levels and tax-payers. The formed interbudget relations national model estimation mechanism does not reflect the real situation with resource providing of the territories and distorts its social-economic dynamics rating (Zenchenko, 2009, p.3).

Moreover, in the course of the problem under consideration analysis, it was clarified that by the present time there are practically no publications, devoted to the working out of approaches to the interbudget leveling national model effectiveness estimation

and proliferation of their test results. Most of the works are based on the analysis of certain criteria of the territorial formations revenue powers distribution quality and do not concern the issues of holding the total estimation. Here belong the papers by Avetisyan (2011), Bahl (1986), Bahl and Linn (1994), Boik (2013), Boadway, Cuff and Marchand (2003), Chernyavsky and Vartapetov (2004), Jack (2005), Kizeev (2011), Kimelman (2010), Liberati and Sacchi (2013), Lundqvist (2015), Marques, Nazrullaeva and Yakovlev (2016), Mello (1999, 2000), Nortman (1971), Pechenskaya and Uskova (2012), Siluanov, Starodubrovskaya and Nazarov (2009, 2011), Staats (1974), Vasilieva et al. (2017), Verbinenko and Badylevich (2013).

The investigation of different approaches to the estimation of interbudget relations organization effectiveness and the practice of their realization enables us to note that by now their conceptual contents are incomplete:

- first, the approaches to the study of interbudget relations' effectiveness are considered separately from the conditions of the state financial system functioning;
- second, most of the approaches are based on the analysis of certain quality criteria of territorial formations revenue powers distribution and do not concern the aspects of carrying out total estimation;
- third, the study of interbudget relations as a trend to boost the tax potential of the territories, which is a key instrument to arise interest in all levels of power and taxpayers in actions and results, as well as in the coordination of their economic interests – all this has not yet become the object of special research.

The above-mentioned circumstances determined the topical character and practical importance of scientific research, in whose framework the complex methodological approach to the estimation of the interbudget relations current national model effectiveness as a trend to enhance tax potential of industrial cities in the Russian Federation is formed.

Methodology

Paying its due to the significant research work, made in the field of comprehending and studying interbudget regulation processes effectiveness, its role in the management of the social-economic development of territories and the state, on the whole, within the limits of the present paper, the authors tried to eliminate the above-mentioned gaps. The methods of economico-statistical estimation effectiveness, proposed by the authors, and covering the current national model of interbudget relations as a trend to enhance the tax potential of the territories, presuppose two stages.

Within the first stage, with the help of statistical research, the interrelation between the volume of interbudget transfers of different kinds (grants, subsidies, subventions and other transfers) and the figures of the integral indicator of the municipal territory tax potential is explicated and analyzed. It is noteworthy, that it is in the process of dependences statistical research that the cause-effect relations among the phenomena are expounded as "the relation of phenomena and processes, when the change of one of them – the cause – results in the change of the other – the effect" (Vasilieva et al., 2017, p.638).

In order to divulge the existing relation, its character and trend between the volume of interbudget transfers into the budget of the territorial formation and the integral indicator of the tax potential, it is proposed to point out factor markers (factors) and

result markers, necessary for the research. As a factor marker, in view of the analysis, we recommend to take the number of grants, subsidies, subventions, and other transfers into the local budget from the higher level budgets; and as a result marker – to take the integral marker, characterizing the level of the territorial formation tax potential.

The close-knit character of the relation is quantitatively expressed with the correlation coefficient figure, as well as the close correlation link between the grants, subsidies, subventions and other transfers, coming into the local budget from the higher level budgets and the integral indicator of the territorial formation tax potential and can be measured by the determination coefficient. The determination coefficient is an indicator, representing a relative figure, characterizing the ratio of the intergroup dispersion in the general dispersion of the resulting marker and reflecting the factor marker influence strength on the formation of the resulting marker general variation (Vasilieva et al., 2017, p.639):

$$R^2 = \frac{\delta^2}{\sigma^2} \quad (1)$$

where δ^2 – is the average square deviation of the mean figures in the resulting marker;
 σ^2 – is the average square deviation of factual figures in the resulting marker.

For the qualitative estimation of the close relation, based on the determination coefficient indicator, it is generally accepted to apply Chaddock ratio, represented in Table 2.

Table 2. Chaddock correlation (Vasilieva et al., 2017, p. 638)

R²	0,1-0,3	0,3-0,5	0,5-0,7	0,7-0,9	0,9-0,99
Relation force	Weak	Average	Notable	Close	Very close

On the second stage the authors propose the calculation of threshold levels of interbudget transfers ratio in the total revenues of the local budgets, where the maximal increment of the integral indicator is noted and it characterizes the territorial formation tax potential, and the balance of economic interests of all the power levels and the tax-payers is kept with the help of the mean balanced figure:

$$\bar{x} = \frac{x_1 f_1 + x_2 f_2 + \dots + x_n f_n}{f_1 + f_2 + \dots + f_n} = \frac{\sum x f}{\sum f} \quad (2)$$

where $f_1, f_2, \dots, f_n$ – are balances (frequencies of the same indicators' repetition);
 $\sum xf$ – is the total of the indicators figure multiplied by their frequencies;
 $\sum f$ – is the total number of integral units.

The calculation of threshold levels in the ratio of interbudget transfers figures in the total budgets revenues of territorial formations is recommended to supply with the found analogous figures by the current date and their comparison.

Results

In this article, there was an attempt to clear up the expediency of the practical application of the complex approach to results estimation of the interbudget relations current national model for the field of investigation – major industrial cities, included in the Ural Federal District of the Russian Federation. Regarding this fact, N.A. Kharitonova, E.N. Kharitonova, and N.L. Levinson noted: "Economic restructuring within the Russian Federation has considerably reduced the number of industrial giants, many of which proved unviable in the new economic conditions. However, those that remain, are leaders in Russian industry, and their success determines the life not only of the local municipalities but often also of the whole region where they are located; as before, they continue to determine the economic and industrial potential of the region" (Kharitonova, Kharitonova and Levinson, 2007, p.250).

The rationality of the research range choice is determined not only by industrial specialization of territorial formations but also by a high dependence of local budgets on the resources of the higher level budgets, that is pointed out by the authors, by the gradual decrease of interest on the part of the municipal bodies of power to expand their own revenue base. In particular, the specific weight of interbudget transfers in the total revenues of local budgets of the Russian Federation Ural Federal District industrial cities during the period under consideration increased from 41,3 % in 2007 up to 48,3 % in 2017, which is reflected in Table 3.

Table 3. The structure of revenues into local budgets of the industrial cities of the Russian Federation Ural Federal District in 2007-2017, % (Calculated by the authors, according to the official data of the Russian Federation Finance Ministry, 2017)

Type of income	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Tax incomes	43,0	41,8	38,3	39,0	40,9	44,8	41,7	42,7	42,0	44,2	39,3
Non-tax incomes	15,7	17,3	14,8	13,5	12,8	11,8	11,8	11,2	13,1	12,4	12,4
Interbudget transfers	41,3	40,9	46,9	46,6	46,3	43,4	46,6	46,1	44,9	43,4	48,3

The results of the first stage, presupposing the divulging of the relation between the volume of interbudget transfers into the Russian Federation industrial city budget and the integral indicator of the tax potential, using the determination coefficient, are represented in Table 4 and are based on the following dependencies:

- the ratio between the scope of grants into the Russian Federation industrial city budget and the integral indicator of the tax potential is expressed by the formula: $y = -5E-15x^3 + 4E-09x^2 - 0,0012x + 103,53$;

- the ratio between the scope of subsidies into the Russian Federation industrial city budget and the integral indicator of the tax potential is expressed by the formula: $y = -8E-16x^3 + 2E-10x^2 - 2E-05x + 0,18$;
- the ratio between the scope of subventions into the Russian Federation industrial city budget and the integral indicator of the tax potential is expressed by the formula: $y = 1E-14x^3 - 3E-08x^2 + 0,0252x - 7704$;
- the ratio between the scope of other transfers into the Russian Federation industrial city budget and the integral indicator of the tax potential is expressed by the formula: $y = 5E-12x^2 - 2E-05x + 23,09$ (Table 4).

Table 4. The degree of relation between the scopes of interbudget transfers into the budget of the industrial city and the integral indicator of the tax potential (Calculated by the authors, according to the official data of the Russian Federation Finance Ministry, 2017)

Factor, X	Result, Y	Existing relation	
		R ²	Force of relation
The total sum of grants into the local budget	The integral indicator of the tax potential	0,9533	Rather close
The total sum of subsidies into the local budget		0,8710	Close
The total sum of subventions into the local budget		0,9888	Rather close
The total sum of other transfers into the local budget		0,7710	Close

Because the determination coefficient reflects the ratio of the result marker Y variations under the influence of the factor marker X, the analysis of calculated figures of the determination coefficient testifies to the existence of a close functional relation between the scope of interbudget transfers into the local budget and the integral indicator, characterizing the level of the Russian Federation industrial city tax potential. In particular, by 95,33% the variation of the integral indicator of the tax potential is preconditioned by the change in the volume of incoming grants into the local budget and by 4,67 % - by the other factors; by 87,10% the variation of the integral indicator of the tax potential is preconditioned by the change in the volume of incoming subsidies into the local budget and by 12,90% - by the other factors; by 98,88% the variation of the integral indicator of the tax potential is preconditioned by the incoming subventions into the local budget and by 11,12% - by the other factors and, finally, by 77,10% the variation of the integral indicator of the tax potential is preconditioned by the change in the scope of other transfers into the local budget and by 22,90% - by the other factors.

The final results of the second stage, presupposing the clarification of the threshold values in the ratio of interbudget transfers in the total revenues of the local budgets, are represented in Table 5, while in the local budgets there is noted the maximal increment of the integral indicator, characterizing the tax potential of the territorial formation, using the average balanced figure.

Table 5. The degree of correspondence in the interbudget transfers ratio figures in the total revenues of the local budgets to the requirements of enhancing the tax potential of the Russian Federation industrial city (Calculated by the authors, according to the official data of the Russian Federation Finance Ministry, 2017)

Result, Y	Factor, X	The threshold value of the interbudget transfers ratio in the total revenues of the local budgets/threshold value of the interbudget transfers special type ratio in their total volume, %
An integral indicator of the tax potential	The total sum of grants into the local budget	43,4/14,0
	The total sum of subsidies into the local budget	43,4/23,1
	The total sum of subventions into the local budget	43,4/56,0
	The total sum of other transfers into the local budget	43,4/6,9

The results of the calculations testify to the fact, that the optimal ratio of the interbudget transfers in the total revenues of the local budgets, stimulating the solidifying and increasing of the territorial formation tax potential, is at the level of 2012 and is substantially different from the figures of 2017, which is represented in a systematized way in Table 6.

Table 6. The detailed structure of the local budget's revenues in the industrial cities of the Russian Federation Ural Federal District in 2007-2017, % (Calculated by the authors, according to the official data of the Russian Federation Finance Ministry, 2017)

Type of income	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Total tax incomes	43,0	41,8	38,3	39,0	40,9	44,8	41,7	42,7	42,0	44,2	39,3
Total non-tax incomes	15,7	17,3	14,8	13,5	12,8	11,8	11,8	11,2	13,1	12,4	12,4
Total interbudget transfers	41,3	40,9	46,9	46,6	46,3	43,4	46,6	46,1	44,9	43,4	48,3
including:											
Grants	23,9	24,0	23,9	21,2	21,3	14,0	16,0	15,2	12,6	13,7	22,0
Subsidies	31,1	23,5	31,1	29,4	29,5	23,1	31,0	32,2	27,1	23,7	29,0
Subventions	37,6	49,7	37,6	40,9	40,7	56,0	46,0	45,6	53,8	55,9	40,0
Other transfers	7,4	5,6	7,4	8,5	8,5	6,9	7,0	7,0	6,5	6,7	9,0

Moreover, the results of the calculations are proved by the maximal figures of the tax incomes' specific weight in the total revenues of the Russian Federation Ural Federal District industrial cities budgets, achieved in 2012.

Conclusions

In the process of achieving the set aim of the investigation, implied in the improvement of existing methodological approaches to the estimation of effectiveness in the current national model of interbudget relations as a trend to enhance the tax potential of the Russian Federation industrial cities, the authors of the article arrive at the following significant results.

Following the comparative analysis of the numerous approaches to the estimation of the interbudget levelling system effectiveness on the level of the Russian Federation industrial cities financial providing, it was clarified that by present, the majority of scientific papers are based on the analysis of separate quality criteria in the distribution of the territorial formations revenue powers and, practically, there are no publications, devoted to the complex methods of research. The authors of the article put forward a way to eliminate the mentioned gap in the modern financial science through exploring and finding grounds for the complex methodological approach to the estimation of effectiveness in the current system of interbudget relations in the conditions of the Russian Federation.

The proposed total method of economical and statistical estimation of the current system, distributing transfers among the budgets of different levels as a trend to enhance the tax potential of the Russian Federation industrial cities is based on carrying out of the following stages:

- statistical investigation of the relation existence, its character and trend between the volume of interbudget transfers of different types (grants, subsidies, subventions and other transfers) and the figures of the integral indicator of the Russian Federation industrial cities tax potential by means of pointing out the factor and result markers and calculating the correlation coefficient;
- the calculation of threshold values of the interbudget transfers ratio in the total revenues of the local budgets, where there is registered the maximal increment of the integral indicator, characterizing the tax potential of the territorial formation, and also the balance is kept between the economic interests of all the government levels and the tax-payers, using the average balanced figure;
- the estimation of effectiveness in the system of interbudget relations under the conditions of the Russian Federation through clearing up the threshold values of the interbudget transfers ratio in the total revenues of the industrial cities local budgets by the current date and their comparison with the optimal figures.

The testing of the proposed criteria and of the represented approach to the estimation of effectiveness in the current national model of interbudget relations, that in a complex way takes into consideration "the interbudget transfers" and "the integral indicator of the tax potential", proved the importance of the achieved results in the process of exploring the proposals to correct the mechanism of transfer distribution, aiming at enhancing the interest of the Russian Federation industrial cities government to decrease the resource dependence from the higher level and to stimulate the social-economic development of territorial formations.

Further, the research will be continued due to the use of the approach, put forward by the authors, concerning not only the industrial cities of the Ural Federal District of the Russian Federation but also the municipal territorial formations in general.

Abstract. *Global and national agendas focus increasingly on the harmonization and development of strong principles, directions and policies, not only concerning economical and financial issues, but also regarding accounting and reporting processes. In this context, governments play an important role in securing adequate levels of efficiency and transparency of public funds spending. This paper analyzes the current framework of standards and regulations in different EU member states and their influences on national public accounting systems. New advances in information technology offer both opportunities and challenges for policy makers in their attempt to improve decision-making processes and promote competitiveness. The current paper uses both quantitative and qualitative methods to describe these processes in various EU member states. Results and conclusions of the study are of interest to policy makers and reflect tendencies for developments according to International Public Sector Accounting Standards.*

Keywords: IPSAS; knowledge management; smart digital technologies; reporting standards; public sector.

Introduction

Modern organizations heavily rely on performant information management systems for ensuring optimal performance and efficiency. This reliance is the result of extensive change processes which have affected accounting and finance not only by the introduction of social policies and reforms in the field (EU, EC, Horizon 2020), but also by harmonization of rules and practices as well as the adaptation of international and European accounting standards (IFAC, IPSASB, 2018). Moreover, in Romania these reforms have affected the accounting system (World Bank, 2008), which was, correlated with the economic, legal, social and political changes that occurred. In this context, accounting system is the representative area for the administrative capacity and have an impact to the countries that have most modified their approaches that can be matched realistically to contextual capacities (Moynihan & Beazley, 2016, pp.3-5).

However, this very complex process cannot be completed without the attraction of the newest information technologies that offer the necessary logistic support. This is true for both private organizations and public entities, but is more complicated for the latter, because of (1) the amount of resources managed by any state, and (2) the need for interoperability between the different EU-member states. The economic alignment

process between EU-member states is one of the priorities of the European Union, focusing on eliminating discrepancies between some of the members; lesser-developed states need in this context an increased effort and attention in increasing their capacity to structure and manage public funds (Dumitrescu Peculea & Mortelmans, 2017, pp.65-82). In this regard, finance, accounting, and audit are in an interdependent relationship, a series of directives (directive IV and VII) along with recommendations to urgently adopt international standards such as IFRS and IPSAS has been issued (IFAC, IPSASB, 2018, 2011).

Finally, yet importantly, in order to overcome the differences between its members, as well as to successfully carry out the harmonization process, there is a great need for innovation, both technical and social. The innovation and modernization of a state are influenced by public administration rationality, which generates competition between public values and searches new opportunities for efficiency growth (Savulescu, 2015, pp.30-33).

The paper is structured as follows: part two describes the harmonization process of accounting practice throughout the European Union by comparing different European states; part three approaches the issue of cross border knowledge management in accounting, part four discusses innovation issues in the international environment and part five concludes the paper.

European harmonization processes in public accounting

The European Union strives to reform the accounting systems of its member states, one of the main objectives being the insurance of comparability of financial data between states, which is required by several European directives and regulations based on international standards (*International Public Sector Accounting Standards* called IPSAS; *European Public Sector Accounting Standards* are so called EPSAS). Another issue is to make performance data more understandable for accounting and reporting processes and additionally, as Caperchione (2015, pp.1-11) argues that harmonizing at the EU level would allow for the production of good quality data to be used more easy. Nevertheless, the alignment with the European legislation (Council Directive 2011/85/EU and so one) demands great-cumulated efforts by all EU-members and an intense need for increased inter-state communication.

Accounting provides an important competitive advantage for an organization that helps create better decision-making value and provides an integrating perspective to the management's strategic functions (Islam & Kantor, 2005). In order to do this, accounting must meet certain demands like accuracy, sensitivity, malleability, timeliness, completeness and consistency of information, without disregarding the legal constraints that are imposed by its fiscal nature.

A study of the Ernst & Young for European Commission from 2012 regarding accounting and audit arrangements throughout the EU mentions communication problems in states such as Austria, Belgium, Cyprus, Greece, Denmark, Germany, Italy, Spain and the United Kingdom. Authorities take some solutions and adopt mechanisms to be aligned in the future and allowing the connection of macro and micro accounting. For example, in Austria are two instruments available for improving the systems, one is the Austrian Stability Pact and the other is regarding to new reporting regulation (Rauskala &

Saliterer, 2015, pp.12-26). Another analysis of the EC approaching national accounting legislation of its member states concerning the diversity of legal requirements in the accounting systems has concluded that a total of three different accounting laws per state are reasonable for the coverage of the main accounting practices of a country.

According to these studies, the countries with the most complicated accounting arrangements are federal states. On the other hand, countries such as Hungary, the Czech Republic, Lithuania, Estonia, Slovakia, Slovenia or Romania have a unique accounting standard, which is applied uniformly throughout the public administration.

In addition, the same studies have determined the accounting models used by the EU-member states (Bellanca et al., 2015, p.25; PwC, 2013):

- Cash accounting – transactions are recorded at the moment of payment;
- Modified cash accounting – a variant of cash accounting which also takes into account unpaid or outstanding accounts;
- Accrual accounting – transactions are recorded at the moment of their occurrence, and not at the moment of payment;
- Modified accrual accounting – a variant of accrual accounting, which records, completed accruals and omits some asset and liability classes.

According to PwC Global survey on accounting and financial reporting by central governments (PwC, 2013) it can be observed that “many countries initiating accounting reforms and moving to the more sophisticated end of the government accounting spectrum”.

In addition, the EC acknowledges a fifth model, a hybrid between cash and accrual accounting, since there are cases of public institutions that use both models such as Italy, or there are cases of different public institutions that use different models despite being administratively linked to each other such as in Denmark (as we can see from the figure 1).

Figure 1. Accounting models throughout the EU
(Ernst & Young, 2012, date based and correlated with ec.europa.eu/eurostat)

According to numerous studies reveals that Scandinavian states tend to adopt accrual accounting (Falkman & Tagesson, 2008), while central and southern European states more often use cash accounting. Austria, Germany and Spain show combinations of the aforementioned models.

IT-based accounting systems part of knowledge management processes

The exploitation of IT-based resources for accounting practice has several advantages on operative levels as well as on strategic levels, leading to both an efficiency and efficacy increase in accounting operation as well as to an enhanced portability and compatibility of accounting data in the strategic plane. Also, by the intensive and extensive use of such systems, knowledge management processes can be introduced to the entity. Figure 2 shows the main components of organizational knowledge management.

Figure 2. Components of organizational knowledge management (Authors' interpretation)

In this regard, the positive influence of IT-based systems can be observed on the same three components of knowledge management (operation, quality, strategy), as shown in figure 3.

Figure 3. Knowledge management elements of IT based accounting systems (Authors' interpretation)

The European Union encourages the use of modern accounting systems based on accrual accounting (see also Milosavljević et al., 2014), which allow for increased transparency levels and are able to deliver complete, reliable and integrated information, in order to improve the quality of management decisions and the accountability of decision makers at all levels of government. In addition, in this regard, the World Bank has launched a strategy for the period of 2012-2015 called “ICT for Greater ICT Impact” for supporting of innovative systems in key fields of public administration activity such as healthcare, education, agriculture, justice, energy and others.

Thus, the implementation of ICT technologies in accounting processes is of vital importance being a sine qua non condition for national and international competitiveness by reducing transactional costs and overcoming geographical and territorial constraints (Yeboah & Oppong, 2014). Also, as underlined by the World Bank, the introduction of such system will lead to economic growth and better delivery of public services and accounting information systems have revolutionized the accounting world (Miller et al., 2016, pp.265-270).

Innovation of accounting processes in the EU

The transition to knowledge based accounting and to performant knowledge management processes is a lengthy and innovation intensive process. Countries that show the greatest innovation levels also are the ones with the greatest HDI and the lowest corruption levels. Innovation leaders such as Sweden, Denmark, Finland, the Netherlands, the UK or Germany also have the most efficient and effective public administrations, as opposed to those that show moderate or even modest innovation rates. Figure 4 shows a multilevel comparison between these countries.

Figure 4. Performance Innovations Leaders (EU, European Innovation Scoreboard, 2018)

For Moderate and Modest Innovators, performance has increased. Figure 5 shows a picture for some countries.

Figure 5. Innovation levels for leading, moderate and modest innovators (EU, European Innovation Scoreboard, 2017)

The innovation of the international accounting conceptual framework struggles in front of national accounting frameworks. Users of accounting information such as experts, creditors, investors, and managers have requested out of necessity an innovative approach to modern accounting practices. The European Union has tried to implement such approaches by issuing numerous regulations and directives, however, the best theoretical basis for the normalization of the accounting profession proves to be the IPSA Standards. Also, the same IPSAS proved in many countries to be the best for the transition from cash to accrual accounting. This lengthy, complex and slow process has proven to be most effective when approached step by step, since it reduced the risk of financial system unbalance.

Figure 6. Overall and financial innovation levels for EU member states (EU, European Innovation Scoreboard)

In addition, countries recording the highest levels of innovation show the most efficient and effective processes of financial innovation. By studying figure 6, the high correlation between these is obvious. According to literature, the relationship between these two dimensions is bidirectional, meaning, that high overall innovation levels lead to high financial innovation levels and vice versa.

Conclusions

The integration of public accounting systems throughout EU-member states is crucial for the future developments of the European Union and is carried out on three levels: (1) harmonization and standardization, (2) intensive and extensive use of ICT opportunities, and (3) high performance innovation processes. However, while concerning harmonization and use of ICT the gaps between countries are not that great, regarding innovation levels the differences are substantial.

The findings of this paper are especially useful to policy makers, in the formulation of alignment strategies to actual and future standards of European accounting. Starting from accrual accounting, processes have to be developed which can ensure the smooth

transition to an integrated accounting system. There are at this time no unitary rules of application of such integrated accounting systems for the public administration, and in countries like Romania, Bulgaria, the Czech Republic, Estonia, Finland, Hungary, Italy, Lithuania, Malta, Poland, Slovenia, Slovakia and Sweden public entities can choose freely what system they use. Additionally, "the key to enhancing adoption of consistent accounting policies within a reporting entity by all controlled entities is regarding to central guide" (ISASB, 2018).

The reliability and transparency of accounting information are vital and this is the reason why numerous studies have been conducted on the importance of public sector transformation (Lapsley & Wright, 2004; Askarany, 2016). By recommendation of the EC this is to be achieved by implementation of "Bookkeeping System", an integrated accounting and financial information storage system. However, EU member states do not have regulations on how to implement such a system. Future developments in the field include the institutionalization of knowledge management processes, and further exploitation of ICT opportunities.

SUSTAINING LEADERSHIP FOR INNOVATIVE BUSINESS

THE DEVELOPMENT OF ENTREPRENEURSHIP IN ROMANIA AT REGIONAL LEVEL: TRANSYLVANIA REGION

Vanesa Mădălina VARGAS

*The Bucharest University of Economic Studies
Piața Romană 6, 10374, Bucharest, Romania
vanesa.vargas1312@gmail.com*

Abstract. *We often hear that the entrepreneur is the engine of the economic environment in a society. This person is very important for the development of the country, takes many risks and is always a leader. Not all leaders must necessarily be entrepreneurs, but in my opinion, all entrepreneurs are definitely leaders. Entrepreneurship is not something known from the beginning of life, as these abilities are not innate, but you can train them and develop them over time. The first step is to start acting. When you have an idea, you do not have to be afraid to express it in a business. Entrepreneurs are doers, not dreamers. Most people develop many ideas during their life, but very few of them put these ideas into practice. Why did that happen? The eternal problem, financing? Bureaucracy? Taxation? Internationalization? Education? Legislation? I will touch and talk about all these subjects in this work. According to a study by The Economist Intelligence Unit for DHL Express, five out of six companies believe that cultural barriers are the most important factor in making the decision to enter a new market. In Romania, this is still not the only one. There will be analyzed a series of main reasons why the number of small and medium enterprises is still small compared to the other member states of the European Union. Primarily, the article starts with the role of small and medium businesses worldwide. After that, a few statements on the situation of SMEs in Romania. Further, we introduce a comparative analysis on the strategy of supporting the SMEs of Romania in comparison with other countries and the effects of the economic crisis on entrepreneurial leaders. The work ends with a case study on the small and medium enterprises from Transylvania, Romania. We will present three important regions from Romania: North-West, Central and West region, and also the effects of the crisis on the evolution of the economy in this part of the country. This study analyses data reports of the National Institute of Statistics. The selected indicators for the current research are distribution of companies by the business sector, the evolution of the number of new registered companies, average number of employees, turnover evolution and GDP evolution for each county. The results are evaluated in order to have an overview and a comparative analysis of the region.*

Keywords: *Innovative leadership; diversity; regional development; unemployment; culturally responsive leadership; regional disparities.*

Introduction

The role of business has an economical component and a social component. That arises from the relationship with other dealers, organizations, institutions, but also from the founders and employees of the company itself. The role of the companies is different from each of these collective entities (Kerbalek, 2002).

One can speak of a formal role and of an actual role of the company. The formal role shows what a business has to do, while the real role shows what a business is actually

doing. The major part of the formal role is contained in the activity of the company, which was defined together with the formation of the company. This role can also be found through the goals that the founder or founders initially identified. The company has a target system made up of one or more haptic targets and several minor targets. One can represent these in a pyramidal form. The main objectives are usually set in relation to sales, net income or market share. For example, one main goal may be to reach a turnover of over 10,000 lei during the first year of employment. The main objective is further divided into other secondary objectives, such as the number of jobs in the company (Kerbalek, 2002).

In the European Union, 99% of companies are SMEs. According to the European Commission, Romania ranked last in EU28 in 2016 in terms of density of active SMEs and 17th place in terms of their contribution to added value. However, Romania expresses itself positively by the ratio of the number of employees as it ranks 8th among the 28 EU Member States (European Commission, 2015).

In Romania, there are 21.3 small and medium-sized enterprises per thousand inhabitants. The European Union average is 42.7 SMEs. The highest densities were recorded in the Czech Republic, Malta and Slovakia (Business Review, 2015).

The critical state of SMEs in Romania has been deepened by accumulating new development gaps following the global crisis. In 2013, there were 15.5% fewer SMEs than in 2008. The proportion of micro-enterprises among the total number of SME's in Romania is 88%, none other than the EU average of 92%. At the same time, the small business class is 10.4%, higher than the EU average of 6.4%. As a main activity, trade remains in first place in Romania, with a share of 40% companies, compared with the average approach of trade in EU of 28% (Mediafax, 2015).

The number of people who believe that the economic environment is favorable for business declined from 19.9% in 2014 to 14.1 in 2015. The deterioration in perception will come in 2015, after the number of People who found the business environment to be favorable rose from 3.79% to nearly 20% (Nicolescu, 2015). According to a report of the European Commission in partnership with Global Entrepreneurship Monitor, Romania is the first country in the European Union in terms of entrepreneurial intentions, stating that 27% of Romanians want to start on their own. The percentage is more than twice the average in the European Union. We are among the first European countries when it comes to how entrepreneurship is viewed in society. 71% of Romanians believe that entrepreneurship can be a good career alternative compared to only 58% of Europeans.

Literature review and general framework

The progress Romania has made so far in SME development is due in large part to the effort, initiative and courage of a few thousand people taking the risk to start on their own. Entrepreneurs are very often the driving force behind economic development. Besides the success, the Romanian entrepreneurs are also responsible for the failures. Therefore, an objective analysis of the characteristics of the Romanian entrepreneurs must take into account even the successes as well as the failures. From the beginning, two major differences between the West European and Romanian Entrepreneurs are

noted: different social background and approach, attitudes and expectations, which are very different in terms of business overview.

Since the late 80s / early 90s, a series of articles has been published, which criticize the "Trait Approach". (Gartner, 1989) even pointed rather brusquely, if the personality of the entrepreneurs important for the business is. The "traits" approach does not lead to his opinion a declaration of entrepreneurship or success because "a startling number of traits and characteristics have been attributed to the entrepreneur, and a "psychological profile "of the entrepreneur assembled from these studies would portray someone who has a great deal of life, full of contradictions, and, conversely, someone so full of traits that he would have to go to a sort of generic 'Everyman' ". He asked then to discuss whether it was not much more important to find out what an entrepreneur is doing to succeed. He clearly pursued one behavioral approach. As a result, traits research has become increasingly insignificant, especially in the United States. There have been a number of long-term studies that "traits" are not considered significant or at least not particularly relevant.

Romanian entrepreneurship is definitely in a promising stage. Despite the country having a lot of potential, the dynamics of change towards a more innovative economy and digital society are poor. There are undoubtedly islands of excellence, and access to a well-educated talent pool is one of Romania's main assets.

Methodology

For assessing the evolution of the entrepreneurship in Romania the attention was focused on the evolution of four main indicators, covering, mostly the period 2008-2016. The source of all data used in the present paper is the Tempo Online Database of the National Institute of Statistics (NIS).

The analysis includes:

- The evolution of the number of firms/1000 inhabitants (only population in working age) for the 2008 – 2016 period, national and county level;
- The evolution of the number of firms/1000 inhabitants (only population in working age) for the 2008 – 2016 period, for micro, small, medium and large companies;
- The evolution of the number of SRL-D firms (started each year) for the 2013 – 2017, national and county level;
- The evolution of the unemployment for the 2008 – 2016 period, national and county level;
- The evolution of the population within working age for the 2008 - 2016 period.

Empirical results

The impact of the crisis on the economic situation of Romania

The absorption of the effects of the crisis has been strongly achieved by 5 channels:

- The foreign trade channel (consequence of the reduction of the main export markets of the Romanian products);
- Financial channel (the reduction of private credit lines of foreign parent companies);
- The channel of trust (increase of foreign investors' appetite in the emerging countries);
- The exchange rate channel (because of the currency devaluation pressure);

- The effect of real estate and balance sheet channel (the impairment of some assets, especially the real estate).

The main consequences of the economic crisis even from the internal, as well as from the external factors are:

- significant decrease in the volume of gross domestic product;
- severe worsening of the budget deficit;
- the decline of the national currency;
- the significant reduction of the current account deficit (European Commission, 2015).

An important source of vulnerability of the Romanian economy was in the perception of investors, the high volume of short-term foreign debt. (20.6 million euros at the end of 2008). The general government deficit has exceptionally exceeded the reference value of 3%. In July 2009, the European Council included Romania in the excessive deficit procedure. As a result, Romania had to achieve fiscal consolidation of at least 1.75% per annum in the period 2010-2012.

At the end of 2009, government debt was 23.7% of GDP at the end of 2009 and matched the 60% reference value of GDP. The national currency was devalued in 2009 at 2.9% in comparison with the euro currency, but the exchange rate developed unevenly throughout the year (CNIPMMR, 2009).

The newly established companies (SRL-D, are companies started under a state scheme by entrepreneurs which are starting a company for the first time) might signal the risk aversion of Romanians and their desire to get involved in a more direct way into the economic gave. The peak was reached in 2013, when the program started and most of those thinking on embarking on this path "jumped" on the opportunity. The decrease that followed was abrupt and it almost halved the number of established SRL-D in 2014 and it was followed by an increase in the coming years. The economic increase that accelerated during the last two analyzed seems to be favoring employees and as a consequence it does not seem to be encouraging entrepreneurship through this governmental scheme. The newly established companies (SRL-D, are companies started under a state scheme by entrepreneurs which are starting a company for the first time) might signal the risk aversion of Romanians and their desire to get involved in a more direct way into the economic gave. The peak was reached in 2013, when the program started and most of those thinking on embarking on this path "jumped" on the opportunity. The decrease that followed was abrupt and it almost halved the number of established SRL-D in 2014 and it was followed by an increase in the coming years. The economic increase that accelerated during the last two analyzed seems to be favoring employees and as a consequence it does not seem to be encouraging entrepreneurship through this governmental scheme.

North-West Region

The North-West Region is one of the eight developing regions of Romania and includes 6 districts: Bihor, Bistrita-Nasaud, Cluj, Maramures, Satu-Mare and Salaj. The surface of the region is 34,159 km², which is 14.32% of the total surface area of the country and has a population of 2,744,914 inhabitants (Popescu, 2001).

The region comprises 421 administrative-territorial units: 6 districts, 42 cities, 398 municipalities and 1823 villages. The region has a strategically favorable geographic location, namely borders with two countries: Hungary and Ukraine, but also borders with other three regions of Romania: the center, the northeast, and the west.

Northern Siebenbürgen (as this region is still called) is a cosmopolitan region, where besides Romanians more than half (52.8%) live in the Hungarian population. This thing has created a unique, cultural identity.

The region had a GDP per capita of 10,100 euros in 2009, i.e. 91.24% of the average national GDP / inhabitant, but only 43% of the average of the European Union. The sectors with the highest contribution to gross value added in 2009 were services (53.81%), industry (26.75%), construction (10.8%) and agriculture (8.64%) (Carta Alba a IMM-urilor din Romania, 2011). In comparison, we have a figure with the number of SMEs in the main sectors of northwestern Romania in 2014.

Figure 1. Distribution of SMEs on sectors in NV region 2014
(Own processing using the data of NIS Romania)

In almost all counties, we notice a sharp decline in the number of small and medium-sized enterprises in 2009 and 2010, a shy return between 2011-2013, but in 2014 we again have a very strong decline, except for the Cluj County, where there was a very slight growth. We have two concrete examples in Bihor and Cluj (as shown in Figures 3 and 4). The sharp reduction was due to the decline in activity in the construction sector between 2009-2014, which was caused by the global economic crisis. The economic leader of the region is Cluj County, where some of the biggest companies are based, such as: Nokia, Dacia or Mol Romania. These have helped the district to emerge more easily and faster from the economic crisis and have promoted the activities of small and medium entrepreneurs.

Figure 2. SME's development, Bihor
(Own processing using the data of NIS Romania)

Figure 3. SME's development, Cluj
(Own processing using the data of NIS Romania)

It is quite clear that the number of employees from the private sector has also fallen. At the beginning of the crisis, SMEs reduced costs and implicitly reduced jobs. That is why we observe a sharp decline in the whole region, as illustrated in the next figure.

Figure 4. Average number of employees, Salaj
(Own processing using the data of NIS Romania)

Figure 5. Average number of employees, Maramures
(Own processing using the data of NIS Romania)

The economic attractiveness of the North-West region

The north - Transylvania development region is one of the most attractive regions of Romania from the economic point of view, to București-Ilfov. This is due to the labor market, the level of wages, the foreign investment, but also the private field and the high level of competition. Suppose, for example, Maramureș County. Here the turnover has always increased positively from year to year.

Important for the region is that the service sector is a very large part of the economy in the developing region. In Cluj, as the development of recent years, tourism and commerce are important areas. But if we look at Figure 8, we notice that there has also been economic growth in sectors such as construction, textile, IT & C and machinery.

This strong development from 2008 to 2014 also happens thanks to the private industrial parks of Cluj-Napoca. Cluj small and medium-sized businesses are very supportive of external transactions, thereby adding value to the region.

Figure 6. Development of the sales of SMEs in Maramures
(Own processing using the data of NIS Romania)

Figure 7. Distribution of SMEs on sectors, Cluj
(Own processing using the data of NIS Romania)

The West Region

The Western region has a surface of 32,034 km² (i.e. 13.4% from the whole surface of the country) and contains 4 circles: Arad, Caraș-Severin, Hunedoara and Timiș. The whole region comprises a total of 42 cities and 276 municipalities (Boari, 1999).

Figure 8. West Region
(*Directia Regionala de Statistica Timis*)

Historically, the region includes the historical province of Banat and part of Ardeal, with a previous economic development and stronger in comparison with other provinces of the country. The region is connected to Hungary, Serbia and Montenegro by European roads. The cities of Arad and Timisoara have airport with modern technologies of aviation (Boari, 1999).

The urbanization of the region (63.6% urban population) is higher than the national average (54.9%) and Hunedoara county has the highest rate of urbanization of the country after Bucharest and 76.9% urban population. The western region population is characterized by cultural diversity. The Romanian community lives between German, Roman, Hungarian and Serbian minorities. In 2002, these accounted for 11.7% of the total population of the region.

GDP per capita has steadily grown since 1998, when it was 1697, to reach 3363,7 euro in 2004. This placed the West region in second place in Romania after the Bucharest-Ilfov region. The most important contributions in the GDP have the service sector and the industrial sector (Carta Alba a IMM-urilor din Romania, 2011). A good indicator that shows us what happened 4 years later is the number of SMEs divided into different activity sectors:

Figure 9. Distribution of SMEs on sectors in W Region 2008
(Own processing using the data of NIS Romania)

In contrast, we see in Figure 11 that after the economic crisis, many sectors, especially services, trade and construction, have fallen sharply. All three were important parts that could increase the gross final product per inhabitant of the region.

Figure 10. Distribution of SMEs on sectors in W Region 2014
(Own processing using the data of NIS Romania)

The Operational Program for the Development of the Regions 2007-2013 had a real success in the West. 788 projects were brought and 430 of these were also developed. The total amount absorbed for these projects was in excess of 850 million euros. One of these projects was "City Business Development Center" in Timisoara, where over 18 new SMEs were supported and over 450 new jobs were created. The beneficiary of this

project was S.C. Modatim Business Facility S.A. The final result was the development of a business center in Timisoara, which includes 5 conference rooms, 11 offices and 121 new parking spaces. The whole value of the project was in amount of over 71 million lei. Another such project, funded by European funds, was the new micro-company ArtFactory, a photo and video studio. Figure 12 shows a summary of the development of the newly established companies in Timișoara in the period 2008-2014.

Figure 11. Development of the newly founded companies between 2008-2014, Timis
(Own processing using the data of NIS Romania)

The number of employees who have participated in training during working hours is much higher among companies in the west than in other regions. (Over 50% of the staff). This has a direct relationship with the number of employees during the economic crisis and their evolution:

Figure 12. Average number of employees in SMEs 2008 - 2014
(Own processing using the data of NIS Romania)

Arad is a place that has developed a great deal even during the crisis. Both the leadership of the district and the entrepreneurship of the population have helped Arad. For example, there is an online platform created especially for entrepreneurs: www.imm-arad.ro, but also many projects such as Academia de Antreprenoriat, Lean Romania, Networking for Entrepreneurs etc.

A total of 14 major projects are underway for the small and medium-sized enterprises coordinated by Consiliul National al Intreprinderilor Private Mici si Mijlocii din

Romania, Filially Arad. The activity of this organization helps the business environment to create new businesses or better develop existing ones.

At the national level, Arad County ranked in 11th place in terms of sales of local companies in 2013.

Figure 13. Development of the sales of SMEs in Arad
(Own processing using the data of NIS Romania)

The Central Region

The Central Region is right in the middle of the country, within the great bend of the Carpathians. With an area of 34,100 km², which means 14.31% of Romania's total surface area, the Central Region ranks 5th. Due to its good geographical position, this region has contact with 6 other regions of Romania. The region includes the following districts: Alba, Brasov, Covasna, Harghita, Mures and Sibiu (CNIPMMR, 2009).

With a population of 2,530,486 inhabitants, the region concentrates 11.7% of the population of Romania. If it was at the beginning the core of the economy of mining (gold, silver, coal and salt), now the main sectors are the processing of metals, chemicals, all branches of light industry and food industry. Agriculture is also very well developed in particular the Industrialplantenkultur, potato culture and livestock.

59.9% of the population lives in the urban areas that comprise the 57 cities of the region. There is a high level of urbanization in Braşov (74.7%) and Sibiu (67.6%), while in Harghita the rural population is dominant (55.9%).

Gross domestic product per inhabitant in 2009 was in the Central Region of 10,700 euros, which is 46% of the average of the European Union, but almost 97% of the average national GDP / inhabitant. There are 11 industrial parks in the region. Seven of them are public property, three privately owned and one in private-public partnership. The total surface of these parks is 436.75 hectares. In the region there are still 5 business

incubators, one of them was founded with European money. District Alba knew a real development and one could observe this also in the gross domestic product of the circle. Growth began in the third quarter of 2009 and from the moment, it rose repeatedly.

Figure 14. Development of GDP Alba between 2008 – 2012
(Own processing using the data of NIS Romania)

In 2013, there were 7,321 active companies in Alba county, about 200 more than in 2012. The number of insolvent companies fell by 54.72% in January 2015, compared to the same month in 2014. One notes That, in comparison with other counties, Alba has a higher number of companies that exist in the tourism sector.

Figure 15. Distribution of SMEs on sectors, Alba, 2014
(Own processing using the data of NIS Romania)

In the Covasna district, the trade and industrialists organized some workshops in the period 2010-2014 with the aim to support and encourage new entrepreneurs to start new businesses. Unfortunately, these trainings have not had the desired effect and the number of newly formed companies has declined more and more. Perhaps, better programs and projects for the circle's entrepreneurs were more helpful to the business environment.

Figure 16. Development of the newly founded companies between 2008-2014, Covasna
(Own processing using the data of NIS Romania)

At the end of 2008, there were 8,585 active companies in Harghita, 87.8% of which were micro-enterprises, 10.1% small businesses, 1.8% small businesses and only 24 large enterprises (0.3%). It is predominantly the companies, the main activity being trade (more than 35% of the total number), processing industry (19.6%) and the real estate sector (13.6%).

Figure 17. Distribution of SMEs on sectors, Harghita
(Own processing using the data of NIS Romania)

The total turnover of local companies reached in 2008 in Harghita nearly 8843 million euros. The trade contribution was over 37% and that of the manufacturing industry about 35%. Gross capital expenditures at the county level totaled 1200 million euros in 2008, most of them in the broadcasting industry.

The most developed circles from the Central Region are Sibiu and Brasov. Sibiu ranks second in the degree of urbanization between the Romanian counties. The existing SME's have developed a lot in recent years and have even absorbed European funds, but also money from the state budget through the 14 programs that are for the demand of small and middle-sized companies. The program best known in Sibiu is the program for the stimulation and development of micro enterprises for the beginners in the business level.

Figure 18. Development of SME sales, Sibiu
(Own processing using the data of NIS Romania)

It can be clearly seen from Figure 20 that, except for the period 2008-2009, when the economic crisis began, the turnover of SMEs has been steadily increasing. Sibiu and its leadership have repeatedly organized conferences on economic issues, but also many information campaigns on the main funding programs. For example, the last major conference was in April 2016 with the theme "Regândirea unei politici moderne pentru IMM-urile europene": these events help small and medium-sized enterprises to develop further and encourage young people to take a look at this environment too.

Another proof of the development of Sibiu County is the construction of a new industrial park on the outskirts of Sibiu. Thirty-one halls are being built there and this investment comes as a result of the constant development of the small companies from Sibiu who have greatly increased their productions over the past year.

The project "Structura de sprijinire a afacerilor destinata IMM-urilor si microintreprinderilor Sibiu-Vest" aimed to develop the business environment in Sibiu and raised 19.7 million lei.

In June 2015, Brasov was in fifth place at the national level with the number of SMEs at 1000 inhabitants. Only Bucharest, Ilfov, Cluj and Timiş have bigger indicators. The national average is from 24 to 1000 inhabitants, while in Bucharest it is 36. Just like Sibiu, Brasov also has a wide variety of conferences for the promotion of state programs with funding for start-ups or how to allocate European funds. One of the most important

events of this kind is "IMM ReSTART". The effect of these meetings can be seen in the next picture.

Figure 19. Distribution of SMEs on sectors, Sibiu
(Own processing using the data of NIS Romania)

Figure 20. Distribution of SMEs on sectors, Brasov
(Own processing using the data of NIS Romania)

Although the leadership of the district tried to promote the SMEs, they attracted few funds from the state budget and could not reach the same level as in 2008 after the economic crisis. 99.6% of Brasov companies are SMEs. Between 2008 and 2014, the number of SMEs fell by more than 13%, from 25,176 to 21,919 small and medium-sized enterprises. However, the most important sectors continue to be commerce, services, hotels, restaurants and construction.

Conclusions

Nowadays, in 2018, it is well known that small and medium-sized businesses are one of the most important parts of a healthy economy. In comparison with the perception from 20-30 years ago, things are changing a lot nowadays and the sector is constantly developing. The SME sector now has a very well-defined structure.

It stands clear that Romania needs to invest in this area for a long time and that it is currently at the beginning. The number of active SMEs is a good indicator that there is still plenty of room for development here. But the SME confidence indicator in Romania also shows good prospects for the development of the business environment. A stable government must acknowledge these problems and continue to build programs for the promotion of SMEs.

The economic crisis has widely damaged the economy. In Romania, the effects came fast and significant, as can be seen from the case study. Thousands of SMEs suspended their activity and others were completely eliminated. Economic growth was eased and the most visible effects were in the area of jobs and volume of sales. One of the key reasons why SMEs did not grow was that people were scared to buy goods or invest in something. Securing the necessary funding, borrowers' congestion, high levels of fiscal strength, higher commodity prices, inflation and delayed payments were other reasons that had an impact on the business environment. According to a study by the Consiliul National al Întreprinderilor Private Mici si Mijlocii din Romania, in the period 2011 -

2014, nearly half of the SMEs surveyed had limited workload, 42.99% have worked in the same access parameters and only 7.3% have had an expense trend.

In 2017, the indicators that may have a negative impact on the activity of SMEs are: the global economic crisis (55.85%), the evolution of the legal framework (43.71%), corruption (42.25%), the inadequate Capacity of Parliament and government to avoid the effects of the crisis (33.16%), the bureaucracy (28.51%), the policy of the Romanian banks against the SMEs (16.65%).

At national level, the number of companies/1000 inhabitants in working age is recovering after the wall recorded due to the effects of the crisis but has still not reached the 2008 pre-crisis levels. The same effect is recorded for the unemployment rate which is on a descending trend but has still not reached the 2008 level. Alarming is the fact that the number of newly established SRL-D companies, a clear indicator of the entrepreneurship propensity is decreasing at the final part of the analyzed period.

As far as the regional perspective is regarded it is obvious that one can identify at least two large areas with two different development speeds. On one hand there are the West, North West and Center areas where the high level of economic development is visible in all analyzed indicators, and on the other hand there are the lagging regions of South-East, South and East.

Abstract. *This paper aims to provide an insight into the current state of mompreneurship in the creative industries in our country. After a synthetic overview of the most important theories in the literature of entrepreneurship, the paper will present a brief secondary analysis of data based on the most relevant statistical research on entrepreneurship in general, conducted by European and Romanian institutions. The conducted empirical research will consist of two qualitative studies that had a complementary role in building a more comprehensive picture of the phenomenon: the self-portrait of entrepreneurial mothers, and the institutional support provided to mompreneurs.*

Keywords: *entrepreneurship, motherhood, creative industries, mompreneurs, women entrepreneurship.*

Introduction

The number of studies regarding female entrepreneurship over the last 30 years has drawn attention to this group of entrepreneurs. Within this group, over the last decade, a subgroup has crystallized: that of entrepreneurial mothers. Although this is not a new phenomenon, it is a new concept that requires a theoretical framework and empirical validation. Although this socio-cultural and economic phenomenon of mompreneurship grew globally, it has not been approached yet by scholars in the Romanian space. For this reason, this paper aims to provide insight into the current situation of entrepreneurial mothers in the creative industries in the country.

The transition to maternity, for most women, changes choices, priorities and career preferences. Mothers' orientation towards entrepreneurship is a growing phenomenon in Romanian space, and its complexity needs to be studied through exploratory empirical research, especially since studies show that mothers build their entrepreneurial identity differently from the rest of the entrepreneurs.

The paper aims to present the main theoretical and practical aspects related to the delimitation of the mompreneurship as concept, as ways of manifestation, the motivations and the processes involved in the decision to start a business, the identification of the favorable factors and the obstacles encountered in the exercise of the double parent-entrepreneur role, as well as the study of this phenomenon in the socio-cultural and economic context of Romania. The purpose of the paper is to identify the main characteristics of the mompreneurship in the creative industries in our country, in the context of the growth of the economic and social role of the creative industries in the last years in Europe in general, and in Romania in particular.

Conceptual delimitation of entrepreneurship. Entrepreneurship in Romania

Schumpeter defines the entrepreneur in terms of the revolution he generates through innovation and “destructive creation” (Schumpeter, 1934, p.156). He is the first who associates the entrepreneur with the innovator (Leovaridis & Gavra, 2013, p. 76). For a specific but syncretic delimitation of entrepreneurship, Robert Paturel uses the definitions of several economists and identifies a set of keywords describing entrepreneurship: risk-taking, uncertainty, innovation, opportunity, the emergence of an organization, the combination of new resources, creating value, creating jobs; he also proposes an own definition: “starting from an idea, entrepreneurship is the exploitation of an opportunity within an organization, newly created or taken up in a first stage, receiving a new impulse through the activity of a single person or a team for which it represents an important change in life, through a process that leads to the creation of a new value or to the saving of the excessive consumption of the existing value” (Paturel, 2007, p.28). Synthesizing the different approaches in international literature, Verstraete and Fayolle (2005, p.44) delimit the research field of entrepreneurship through four paradigms: detecting or exploiting a business opportunity, creating an organization, creating value and innovation.

Over time, schools of thought have been formed to investigate entrepreneurship from different points of view. Thus, six models of entrepreneurship have emerged associated with six schools of thought grouped into four categories of themes (Ciocchina, 2013, pp.45-47). Viewed as a whole, these schools of thought provide a global picture of the entrepreneur and his qualities: charismatic, innovative, motivated (the School of “Big People” in Entrepreneurship and the School of Psychological Characteristics), a person who sees opportunities and can capitalize on them (Classical School of Entrepreneurial Thinking), a person who efficiently allocates resources and whose actions and style describe the pattern of a leader (The School of Management in Entrepreneurship and The School of Leadership in Entrepreneurship), a person who constantly adapts (The School of Intrapreneurship). The importance of these schools of thought lies in the overall vision of entrepreneurship that they offer through the complementarity of the angles of interest and the themes approached by each. The main implications of entrepreneurship are divided into four categories: job creation and participation in economic growth; increasing competitiveness towards accelerating productivity; developing individual potential and fulfilling societal interests. The increased interest in the attainment of *entrepreneurial society* describes the favorable attitude towards entrepreneurship and the “valorization of entrepreneurship as a way to achieve social and societal goals” (Leovaridis & Gavra, 2013, pp.79-80).

Many studies on entrepreneurship conducted in our country raise the problem of accessing funds (92% of the entrepreneurs), of the lack of support by the Romanian legislation (58%), the lack of a fiscal environment favoring entrepreneurship (73%), the lack of cooperation between the state institutions, associations and the education system that should support entrepreneurship (87%) (Ernst & Young, 2013). However, according to *Eurobarometer 354*, most Romanian respondents who do not work on their own consider entrepreneurship to be a desirable situation for them (58%), compared with only 37% of Europeans (European Commission, 2012a, p.5). Women show a lower entrepreneurial spirit, preferring to a greater extent to work as employees (63% compared to 53% of men), while men are more inclined to entrepreneurship: 42% of men would like to open a business, compared to 33% of women (European Commission, 2012b, p.5). The research conducted by national experts comes in support of these ideas, presenting an optimistic entrepreneurial framework, in which they measured the courage and intent to start a business: more courageous are young men (25-34 years) from urban area, with higher education and high personal incomes, at the opposite end being women, elderly or low-income people, who have less enthusiasm about the intention to start a business (360insights, 2013). Another recent study conducted by Ernst&Young, *Romanian Barometer of Startups 2016*, confirms that a Romanian start-up entrepreneur typically is 25 to 35 years old, works 10 hours a day, is at the first entrepreneurial initiative, wins below 1000 euros a month and goes at least once a week to a networking event (Ernst & Young, 2016a, p.4). On the other hand, *Romanian Barometer of Entrepreneurship 2016*, based on questionnaires applied to 350 businessmen from Romania, showed the following characteristics of the "local entrepreneurial ecosystem": the experienced Romanian entrepreneur is around 40 years old, he works hard (about 9.6 hours a day) and takes risks for the success of his business (Ernst & Young, 2016b, p.4). This profile matches the European entrepreneur, only with a broader age spectrum (25-49 years old, compared to 25-40 years old for Romania) (European Commission, 2014, p.17). The same study shows that 62% of women entrepreneurs in Europe are aged between 15-49, being on average slightly younger than men entrepreneurs aged 15-49 (60%) (European Commission, 2014, pp.17-18).

Reasons for starting a business are the desire to have a higher quality of life and to achieve financial independence. The main barriers to entrepreneurship are the chosen career path (21.2%), the unfavorable socio-economic context (14.6%), the lack of training or skills required by an entrepreneur (14%) (Lițoiu & Negreanu, 2012, pp.17, 42). The effort of institutional discourse in recent years to stimulate investment and involvement of Romanians in various training programs in this direction is showing result within a positive attitude of Romanians (78%) who consider entrepreneurship as an excellent career alternative compared to the European average of only 58%, doubled by the high percentage of Romanians who believe that entrepreneurs have a privileged status in the society (74%) (GEM, 2012).

Creative industries - theories, models, economic and social role, entrepreneurship in creative industries

In the last few years, different definitions have been developed to describe the specific features of the creative industries, where notions such as the "creative sector", "creative industries", "cultural industries" or "creative economy" refer to a wide range of activities involving the commercial exploitation of creative and artistic work. Some European

official institutions (European Commission, 2010, pp.5-6) make a distinction between terms such as “cultural industries” - those industries that produce and distribute goods or services that have specific attributes, uses or purposes that represent or transmit cultural manifestations, irrespective of the commercial value they carry (theatrical arts, visual arts, cultural heritage, film, DVD and video, television and radio, video games, digital media, books, music, and the press) and “creative industries” that use culture as a resource, giving a cultural dimension to the products, although the results of their work are mainly functional - architecture, graphic design, fashion design or advertising. Throsby's concentric circle model (as cited in Connor, 2010, p.56) places creative ideas in the pool of mainstream creative arts where, in the form of sound, text and image, these ideas are diffused outward through a series of “concentric circles” that delimit the cultural and commercial proportions, the decrease of cultural content being directly proportional to the distance from the center, the movement towards the outside being in a specific order: central creative arts (literature, music, performing arts, visual arts), followed by cultural industries (film, museums and libraries), wider cultural industries (heritage, publishing, audio, television and radio, video and computer games), related industries (advertising, architecture, design and fashion).

Considered one of the most promising areas in developing economies, the creative industries benefit from both a diverse mix of consumers and creative resources that drive growth in other sectors (Ernst & Young, 2014, p.4). In other words, the creative and cultural industries contributed in 2012 to 4.2% of Europe's GDP. This economic sector is the third largest employer in Europe, following the construction and food industry related services. More than 7 million Europeans are employed directly or indirectly in creative and cultural activities - 3.3% of the EU's active population. Of these, the theatrical arts (1,234,500), the visual arts (1,231,500) and the music (1,168,000) employ more than 1 million people each, followed by advertising (818,000), books (646,000) and film (641,000) (Ernst & Young, 2014, p.10).

Some authors (Marco Serrano, Rausell-Koster & Abeledo-Sanchis, 2014, pp.81-91) have shown that there is a significant bidirectional causality between regional prosperity (GDP per capita) and employment intensity in the cultural and creative industries, concluding that there is a “virtuous circle” fueled by these industries. In some European countries, creative industries report a higher level of innovation than non-creative industries: for example, in the UK over 40% of creative industries report internal use of R&D resources, over 20% report use of design and almost 35%, innovations in marketing; each of these percentages is greater than that of non-creative organizations (Bakhshi, McVittie & Simmie, 2008, pp.21-22).

Due to the dense population, its cultural market, its cultural heritage, and the highly talented creative class, Europe has long been a source of organizational leadership in creative industries, whether it's about renowned international corporations or just small avant-garde startups (Ernst & Young, 2014, p.18). These businesses take on the pioneering role in various fields, from music, where Universal Music Group is the leader, to television - Endemol, to publishers - Pearson and Hachette Book Group, to video games - Ubisoft and Supercell, and advertising - WPP and Publicis. Europe becomes more than an innovation hub, creating and developing new business services and models, such as the Swedish Spotify and the French Deezer (Ernst & Young, 2015, p.45). Colette Henry (2007) encourages the use of best practices in finding solutions to maximize the potential of creative industries in the global economy; it focuses on how

investors and entrepreneurs can work together to create new spaces for “entrepreneurial energy” within the various creative industries in these times of rapid digitization. David Rae (2004, pp.492-500) also explores how entrepreneurial abilities and identity are learned in the creative industries and media, proposing a conceptual framework of entrepreneurial learning in the creative and media sectors, based on social learning.

A study called “The attractiveness of the creative professions and entrepreneurial orientations of young people in creative fields” (Moise, Jderu & Cristea, 2012, pp.2-14) presents the results of qualitative research on the preferences of young Romanians for creative professions and their entrepreneurial orientation. Thus, in the top of the most attractive creative professions among young people, the first positions are occupied by the journalist (12.2%), the photographer (11.8%), the architect (10.9%), followed by IT programmer (9%) and fashion designer (8.3%). Moreover, 70% of young people would choose the first profession option as a creative profession. The degree of notoriety of these professions influences the perceptions of young people and maintains their desirability for these choices, which is why architecture is considered one of the most popular creative professions in society. Of the young people who mentioned the creative industries as their first job option, 57% say they would open their own firm in the chosen field if they had the necessary material resources. The preferred professions of those oriented to entrepreneurship are photographer, architect, fashion designer, IT programmer and journalist. As for the preferred business field, 26% of them say they would invest in hotels or restaurants, 22% would focus on creating online stores (online shopping sites), 10% would invest in agriculture, 9% in construction, 7% in transport, and only 6% in creative industries such as music recording studios, publishing houses, advertising etc.

Female Entrepreneurship in Romania. Mompreneurship

Towards the end of the 1990s, “female entrepreneurship” became an independent research area and was a popular topic in the media and for the political debates on economic markets and employment. In addition to the characteristics and professional achievements of female entrepreneurs, research has now extended to health, maternity issues (Williams, 2004, pp.467-485), family positioning, lifestyle and work-life balance (Schindehütte, Morris & Brennan, 2003, pp.94-107). Increased attention was paid to the study of women-led businesses that covered topics such as growth and performance, management style (Brush, 1992, pp.5-31), financing, human capital, labor markets (Bird & Brush, 2002, pp. 41-65) and social entrepreneurship (Carter et al., 2003, pp. 15-17), among others. Although important steps have been taken in the study of female entrepreneurship, this field is far from being exhausted, with a variety of extensions and further investigations to be made (Minniti, 2009, p.620).

Naudé (2010, pp.1-12) aims to explain the gender gap in business initiation in countries with similar economic development levels, taking into account non-economic factors such as culture and institutions. The authors are particularly concerned about the impact that “gender institutions” or “gender culture” have on the decision of a person, whether male or female, to start a new firm. In this context, both a post-institutional approach based on economic studies and organizational theory seem promising (Reskin & Bielby, 2005, pp.80-86), as well as other approaches in the sphere of the economy that

integrate tools and methods from fields like anthropology and ethnography (Chamlee-Wright, 1997, pp.20-25).

The field studies developed in Romania provide a socio-demographic profile of the local female entrepreneurs. First, there are the potential entrepreneurs (not having their own business, but involved in activities to start a business) have an average age of 42 years and work experience for about 15 years, half of them (49%) have studies in management and business management; the men in this group of potential entrepreneurs are of similar age but have a lower work experience (12 years), most of them (55%) having management experience. Female owners of newly established firms (up to 2 years old) have an average age of 37 years and a 10-year work experience, most of them (73%) having studies or training in management and business management; in comparison, the men in this group are one year younger, have one year less work experience and 55% of them have management experience. In addition, more men than women have entrepreneurial examples in their families, and these examples are mostly masculine for both men and women (Driga & Gonzáles, 2009, p.12). "The main motivation women invoke for their involvement in entrepreneurship is the opportunity to improve their quality of life, followed by the possibility of earning money, and therefore to be realized on a personal level, unlike men, for whom the main entrepreneurial motivation is the opportunity to earn money, followed by the improvement of the quality of life and only for the last place they take into consideration the personal level" (Leovaridis & Gavra, 2013, pp.94-96).

In our country, of the total number of company owners (1.2% of the total population), 75% are men, so only 25% of women. Of these, 36% are aged 35-44, 32% between 45-54 years and 18% between 25-34 years, the rest being under 25 or over 55 years old. Of the self-employed (35.1%), only 28.7% are women, compared with 71.3% men. Of these, 21.9% are aged 35-44, 20% between 45-54%, and 17% aged 65 or over, with the remainder being between the 25-34 and 18-24 (National Institute of Statistics, 2017, pp. 128-132). The "Global Entrepreneurship Monitor" evaluates women entrepreneurship in Romania as being "out of necessity" rather than "seeking the opportunity". What it means is that instead of being motivated by the existence of opportunities - 20% of respondents, most women (50%) said that they would not have made it otherwise. The other 30% mentioned both variants, "being able to fit into a push-pull model, where the necessity and identification of opportunities were the entrepreneurial mobiles" (GEM, 2010).

The idea that women are more averse to risk has been a topic that has long been studied in recent decades, and studies by Rutterford and Maltby (2007) seem to confirm this: "women are more inclined towards risk-bypass behaviors and tend to take more moderate risks than men" (Ivan, 2013, p.128). The metaphorical naming of the phenomenon, *nesting instinct*, is not accidental. In their study on women's relationship with business-related risks, especially regarding investments, Rutterford and Maltby (2007, pp.315-320) stressed the existence of natural, biological precaution of women in terms of risk, protection and care of the family, but also a fearful behavior towards risk, since all interactions present a certain degree of uncertainty. "As most of the economic and entrepreneurial interactions have an above-average level of uncertainty and involve assuming risks, we can associate the concept of *nesting instinct* with female entrepreneurial behavior. If risk aversion is a biological component, innate, specific to women, with obvious adaptive valences, we can wonder to what extent a society may

want more female entrepreneurs and women involved in investment rather than in saving plans creation" (Ivan, 2013, p.128).

Davis and Shaver (2012) complement those previously written from a mother's point of view, which seem to be more prone to risk than women in general, with a desire for growth and a much higher motivation than men or women entrepreneur. Lewis and colleagues use the theory of borderless careers as a perspective to explore and analyze the moment of transition in careers for women, and specifically the event of maternity in connection with the transition from employment to self-employment (Lewis et al., 2015, pp.21-37). Introduced by some as "the new feminism", the new rapidly growing phenomenon – *momprenneurship* - is an impugnable and disputed subject. The article raises the question of whether such transformations in working practices (incorporated in the figure of a *momprenneur*) have the potential to offer more options for working mothers, or if they allow the reappearance of inappropriate expectations and arrangements within families (Ekinsmyth, 2013, pp.1230-1248).

In addition to this article, Kochman (2014) lists five reasons why mothers have the chance to be successful entrepreneurs. The author begins his argument with describing the resemblance between growing a child and growing a business, where the necessary skills intertwine, arguing that motherhood not only provides the right business training but, as other studies show, venture capital companies led by women typically earn higher earnings by 12% and start with a three times lower capital. In addition, women-led companies are more resistant to financial crises than their male-led counterparts. His question is why only 10% of the founders of a business are mothers? Professional barriers to networking, limited access to funding, and lack of models to follow can be some of the reasons why they are more reluctant, but the real reason is that most fear that they cannot combine maternity with intense entrepreneurial life. The author claims that mothers acquire many of the skills that are essential, as entrepreneurs. These include working under pressure, bargaining skills, creativity and the ability to combine the most appropriate resources, controlling pride and pursuing a greater purpose, long-term thinking, motivation to continue despite bad situations and so on. While entrepreneurs have the choice to quit their business, a mother will never be able to give up a child. This feeling of challenge and triumph regardless of obstacles turns mothers into heroines, and furthermore, in successful entrepreneurship.

Regarding gender inequalities within the creative and cultural industries (CCIs), these were insufficiently explored. Global research that has studied gender inequalities in various industries has revealed that there are patterns of women exclusion based on their social class, race or ethnicity. These inequities are amplified by the precariousness, informality, and requirements of program flexibility, general features describing work in contemporary creative industries. Moreover, women, and mothers, in particular, are disadvantaged by the interconnected boundaries between home - job roles, unpaid work – paid work, by new social pressures built around self-identity, sexist attitude and gender pay gap. Understanding the specificity of women's work in the creative industries in the neoliberal economy involves understanding their problems in regard to gender differences (Conor, Gill & Taylor, 2015, pp.5-20).

Although it is not a new phenomenon, *momprenneurship* is a new concept that is still looking for a theoretical framework and empirical validation (Lewis et al., 2015, pp.21-23). Studies show that women build their entrepreneurial identity either through

resistance to gender differences or by assuming and embracing femininity (Richomme-Huet, Vial & D'Andria, 2013, pp.254-260), but entrepreneurial mothers overcome these stages guided by their natural and biological instinct called metaphorically the “nesting instinct” by researchers (Ivan, 2013, p.128).

In Romania, a key issue in the discussion of women's savings versus investments trends is the 'financial literacy', namely their education in this respect, both at the level of their competencies and knowledge, as well as in the level of confidence and interest towards knowledge in the financial or economic area, since gender-differentiated schemes are also closely related to this. The value context and the cultural-religious space play as well a particularly important role in building the environment in which these entrepreneurial programs develop. In some countries, “working with money” is considered to be especially the men's job, a “dirty” action that dishonors the woman, so financial literacy programs are facing real challenges (Ivan, 2013, p.134). These aspects of culture are reflected directly in the small number of women entrepreneurs, both in Muslim religion countries, where the percentage of female entrepreneurs is only 5% and in countries that strongly adhere to paternalistic values: Romania, Russia, Latvia, where gender roles indicate rather an association between the financial power and the masculinity (GEM, 2010).

“Mompreneur” is a neologism made up of the terms “mother” and “entrepreneur”, and starts to have its own place in the dictionary of the researchers interested in the contemporary aspects of entrepreneurship. The “mompreneur” embodies the transition from offline to online in the era of digitization, US News & World Report attempting to dismantle the myth of “mothers with ideas working from home” on the grounds that any innovative idea sells, putting mothers among first-time innovators (Palmer, 2011). Creating associations to support this trend was inevitable. Pioneers from Canada started what now became the largest online resource website, *Mompreneurs*, with the purpose of providing support, education and national promotion to all mother entrepreneurs. This online community has become a milestone in the world of mompreneurship through its many projects and events, including the Mompreneur Awards, an event that rewards successful mothers, or the Mompreneur Momentum, the nonprofit organization dedicated to helping mothers access resources. The core values of this association are collaboration, integrity, unconditional support, inclusiveness, trusting community and empowerment.

In Romania, there are two such communities: Happy Moms and Mamprenoare. The purpose of Happy Moms association is “to offer support in the harmonious and healthy personal and/or professional development of pregnant women, mothers, children and family in general” (see Study B). By creating the *Business Mom* program, an entrepreneurial school of mentoring and motivation addressed to mothers, a large community of entrepreneur moms was created. They are participating in conferences (M.A.M.A.), educational training, personal enhancement groups or free courses available to them for personal and professional development as entrepreneurs. Moreover, they are encouraged to participate in the business ideas contest developed with the purpose of sharing resources through an incubator of start-ups for entrepreneur-mothers.

The Mamprenoare community is created as a sub-company supported by Level up Vision, a training firm in the areas of branding, communication, public speaking, and leadership. Its mission is to “provide support, education, and inspiration to

entrepreneur mothers, and to be there in their first steps towards entrepreneurship in a business environment” (see Study B) by providing a unique platform where mompreneurs connect and promote their businesses in Romania. The founder herself offer strategic business advice, by organizing meetings periodically and locally with entrepreneur-mothers to exchange views and get support from the community, by providing ideas and solutions to promote themselves with a small budget and last but not least, by organizing courses, seminars and conferences on various business-related themes. Among the most well-known events of this community are the “Successful Mother and Entrepreneur”, an event that takes place regularly in the big cities of Romania, but also “Children and Money” a financial parenting workshop which helps mothers juggle with their finances for both their businesses and their children.

Besides the above-mentioned communities, a WAHM Romania networking community was created as part of the global Work at Home Moms phenomenon, as “social initiative to support active mothers and make them aware of their vital importance within the family”. From the very first few days since the launch of the idea, the community grew remarkably thanks to the hundreds of interested mothers who enthusiastically joined the Facebook page dedicated to Work at Home Moms. The project then crystallized by setting up the Work at Home Moms Association. “This association aims to support creativity and innovation by defending intellectual property rights” (see Study B). The group relies on creating a community where mothers can communicate and can provide support to each other, where they can collaborate, discuss work ethics or the legislation in place, organize seminars or meetings on various business-related themes and prepare mothers for the competitive market.

Field research on mompreneurship in the creative industries in Romania

Research methodology

In choosing the research methodology we took into account the specificity of the investigated topic and the questions we want to answer. Being an unexplored field in the scholar literature in Romania, our study focuses on investigating systematically a new area of interest regarding female entrepreneurship to serve as a starting point for further quantitative studies. The decision to choose qualitative methods, with their limits and advantages, was encouraged by our desire to explore a newly formed socio-cultural and economic phenomenon, rather than measuring the intensity of its manifestation. The choice of research tools thus proceeded from the nature of the selected methods and techniques. To conduct in-depth exploratory interviews, we have built a semi-structured interview guide for entrepreneur mothers and another semi-structured interview guide addressed to representatives of institutions involved in creating the socio-cultural and economic context for mother entrepreneurs. Data collection was done using face-to-face interviews with previously prepared interview guides. Each interview lasted between 60-90 minutes and the responses were noted on the spot by the interviewer. Interviews with the first group of subjects took place between April 5-30, 2017 and with the second group of subjects, between May 2-15, 2017.

The overall objective of this study is to outline the profile of mompreneurs in the creative industries in Romania and to identify the main characteristics of mompreneurship in this sector. In fulfilling this objective, the research was divided

methodologically into two different studies, complementary to compiling a more comprehensive picture of the phenomenon: the self-portrait of entrepreneur mothers (A) and institutional support for mompreneurship (B).

The empirical data of the first study (A) was collected through in-depth exploratory interviews addressed to a number of 21 entrepreneur mothers working in the creative industries in Romania. The goal was to discover the experiences and challenges faced by them in balancing the double responsibility of maternity and business leadership. A respondents' selection strategy was adopted, in which participants were recruited by searching for different networks and clusters, articles and blogs about mompreneurship, provided they were entrepreneurs in the creative industries. The subjects of the first part of the research were selected from different localities, age groups, levels of education, and having different businesses as seniority and specificity. Their businesses vary from decorative arts, architecture, branding and communication consultancy to fashion design or francophone publishing. Their age ranges from 27 to 55, the level of education between high school and masters. Most women are married (17), some are in a second marriage (3), and the rest are single mothers. The 'age' of business varies from 6 months to 17 years. Mothers' locations cover areas of interest in Romania and extend from Bucharest to Cluj, from Constanta to Iasi, Brasov, Suceava, Barlad, Deva, Craiova and others. The specific objectives of this study (A) were: 1. To identify the grounds and factors that have led mothers to establish a business in the creative industries. 2. To identify the favorable factors and barriers to business development. 3. To explore the characteristics of the mother's status in relation to the launch of the business. 4. To explore the opinions on governmental, social and cultural support to entrepreneur mothers.

The second study aims to analyze the situation of the mompreneurs in terms of institutions recognized as having an important role among entrepreneur mothers (LevelUp Vision, Happy Mom - Business Mom, Work at Home Moms), or entrepreneurs in general (Start Up Nation, Chamber of Commerce, Directorate of Entrepreneurship and Programs for SMEs). Semi-structured interviews aimed to identify the characteristics of the mompreneurs from an external perspective to their group, thus guiding the discussion towards the role of mompreneurs in society, as well as vice versa - the influence of society on the development of this subgroup of female entrepreneurs, all from an objective point of view, external to the group. For this part of the survey, we interviewed 5 representatives of private and state institutions: Start-Up Nation, Level Up Vision, Happy Moms, Chamber of Commerce, Directorate of Entrepreneurship and Programs for SMEs. The specific objectives of this second part of the research are 1. To identify the main characteristics of the entrepreneurial mothers in the creative industries. 2. To analyze the external factors that influence mompreneurship in starting a business. 3. To identify the measures taken to support this subgroup of female entrepreneurs.

Research Results

A. The self-portrait of mother entrepreneurs. Analysis of data obtained through interviews with entrepreneurial mothers

By pursuing the specific objectives, the study begins with the analysis of the motivations, aspirations, and factors that encouraged mothers to start a business in the creative

industries sector. For a more in-depth analysis, we grouped the answers into pull and push categories. As defined by the authors Schjoedt and Shaver (2007), push factors are elements specific to the field of necessity, such as inadequacy of family income, lack of job satisfaction, difficulty in finding a stable job, need for a flexible program due to family responsibilities. Pull factors refer to the desire behind an action, like the desire for independence, the need for self-fulfillment, the desire to become an entrepreneur, the desire for social status and financial prosperity.

The study on entrepreneurial mothers revealed that the main motivation, and the most often cited (14 of 21 possible mentions), is the desire to turn passion into a source of income, or simply to turn a hobby into a business. This is followed closely by push factors such as *"the desire to have a flexible program tailored to the needs of children"* (P.O., 34, Constanța), the desire to work remote, the freedom to choose clients and the freedom to influence the direction of the business, as well as the education of their children (*"I did not want to raise my children with a babysitter..."* (B.P., 36, Iași). Other mompreneurs mentioned that they are highly motivated by their clients - receiving positive feedbacks from happy customers makes them want to grow the business, evolve, do what they like and work for themselves in order to acquire financial independence. We find that there is a balance between the need and the desire to start a business, and although the pull factors seem dominant, financial interest is the cornerstone of the development of any business. The specificity of creative industries has an important role for entrepreneur mothers in terms of their freedom of expression, opening up the market and increasing demand in recent years for various products and services in the sector.

The study also aimed to identify those factors that encourage and facilitate the start of a business by mothers. The responses of entrepreneurial mothers were related mostly to the help of the partner and family, proof of the mentality change regarding the role of a woman in the house. Other encouraging factors include high demand in the areas in which they operate, opportunities for online promotion (especially Facebook) and previous experience in the field.

We studied then the obstacles and barriers that entrepreneurial mothers have encountered in creating or developing businesses. The challenges faced by mompreneurs have varied origins and reflect, on the one hand, the old-fashioned mentality and, on the other hand, the lack of preparedness and support from the state. The main obstacles faced by entrepreneurial mothers are the lack of institutional or government support (and hence the lack of capital), the bureaucracy - which is very complicated and difficult, high taxation and the lack of organization of legislative services (*"I stood for 2 hours at number 2 counter, where I was guided after spending another half an hour on the queue, to find out that in my case the problem could only be solved at the number 1 counter, because only that person was competent"* (I.A., 29, Râmnicu Vâlcea). Another challenge for mothers is the copying of business and the unfair competition. A specific reason mentioned by one of the mothers - *"the home area (rural area), where I have internet only through a router that is very slow [...] and the nearest courier company is at 30 km"* (A.B., 27, Suceava) - draws attention to the need to develop an infrastructure that allows the development of the phenomenon of mompreneurship (and not only) in rural areas as well.

An extremely important barrier to starting a business as a mother is the lack of credibility on the market, as a consequence of a mentality that cancels the woman's role

outside the home. *"We face a hostile environment"* (S.T., 38, Sibiu), *"with stereotypes and old-fashioned thinking - condemning us that instead of taking care of the children and the husband who brings home money, we are looking after businesses and money, not after the saucepan"* (A.B., 27, Suceava). Moreover, *"although many businesswomen are mothers, this is not brought forward, on the contrary, it is diminished in order not to show weakness"* (E.A. 33, Bucharest); *"The general attitude is a suspicious one and a little discriminatory..."* (M.A., 46, Bârlad); *"Mother entrepreneurs are often confused with people who do something funny while the baby is asleep to feel useful"* (N.I., 31, Alexandria); *"I would like to convince the world that entrepreneur mothers are responsible, serious women, that deliver quality products and services"* (L.T., 40, Bacău).

Exploring the characteristics of the motherhood status in relation to the launch of the business was a key point of this study. According to the data, mother entrepreneurs started their businesses no sooner than 6 months after their birth, but this time varies for each mother, as some mothers have started their businesses only after their children have grown up. Often the idea of building something on their own started on prenatal leave, either because of the desire to experience something new, either due to an attempt to *"fill up the free time which I was not used to"* (P.F., 28, Deva).

In our attempt to study how mompreneurs relate to entrepreneurial success, we included in the research questions related to business specificity, number of employees, legal form. Our research revealed that mompreneurs are especially dedicated to small businesses or medium-sized businesses because they can thus fulfill their family-work responsibilities this way. They have between 2 and 9 employees. Each entrepreneur has its own perception of the importance of success. Some look outward, measuring success through traditional business parameters (income, customer satisfaction, loyalty etc.); others use qualitative criteria that reflect self-esteem. However, mothers measure success differently from men (who rather think about job creation, profitability) because of their motivation, as we find out in our study, it is not purely economic, but personal: such as the desire for independence, to follow their passion, the desire for self-fulfillment etc.

Entrepreneurial success, according to the interviewed mothers, consists in the freedom to support yourself from pursuing a passion, trusting your road to success, work, perseverance, innovation (*"high-quality products, customer satisfaction, impeccable execution, fair prices, and customer satisfaction are factors that ensure long-term success"*, L.I., 39, Timișoara). Mothers are recognized for their involvement in the delivery of services or products (*"I dedicate myself to every client as if they were my only client"* - P.F., 28, Deva), succeeding where many big companies do not: an exceptional customer service. Self-confidence and work satisfaction are also important parameters in measuring success. Another important part of success is building relationships with customers, community members, and other businesses. Networking between mother entrepreneurs is also a source and a resource for them. Community support is very important to mothers, it is the place where *"you can affirm yourself outside the business, within a community"* (E.B., 48, Miercurea Ciuc).

Furthermore, the researchers wanted to identify the extent to which entrepreneurial success interferes with success as a mother, which is why we have emphasized on the exercise of this double role. Interviews with entrepreneurial mothers revealed that success is subjective and that although they are interested in financial profit, this is not

their main purpose, but the balance between the roles is crucial. From mothers' answers, we could identify three main factors that help balance the dual role: the family - the help of partners, grandparents, uncles, aunts; the community of mother entrepreneurs (*"I have no one, but to the online community of mothers"* (L.T., 40, Bacău), and factors that derive from personal skills (*"Balance comes from the fact that I am a very well organized person, who knows how to prioritize their activities very well"* – N.M., 31, Buzău; *"Balance comes from chaos, if you're struggling with chaos means you're doing something"* - D.L., 29, Gherla).

The following questions aimed to identify the internal and external factors that might influence the mompreneurs community. Internal factors refer, first of all, to the affiliation of entrepreneurial mothers to groups dedicated to them, to participation in conferences or training addressed to them, but also to building their image within the group through the specifics that the role of mother brings to the status of an entrepreneur. External factors portray the external image reflected in society, the social perceptions, and thus the advantages or disadvantages they face because of the status of mother entrepreneur. We look back at the internal factors and note the particular importance that affiliation to the entrepreneur mothers' group has on these women: *"Yes, with the help of the Work at Home Moms community I can say that we have found real help in networking especially through real and constructive feedback we give and receive from each other"* (I.B., 55, Bucharest). The activity of the mothers in these groups includes networking, promotion within the group, mutual support, exchange of opinions and feedbacks related to products or services, or simply advice for various situations that might arise. However, many mothers admit they are not affiliated with these groups, or that they do not participate in training addressed to them because *"until recently I did not even know about the existence of these groups"* (L.I., 39, Timișoara).

The views on the socio-cultural context and the opening of the market to the entrepreneurial mothers are of a positive overall tone, and the hope of a prosperous future is dominant: *"I think we are mompreneurs at the right timing, culturally speaking, and I trust that things will get even better in the future"* (P.O., 34, Constanta); *"I think that society is beginning to be more open in this regard and to support as much as possible the mother entrepreneurs by promoting them and buying the products they make"* (N.M., 31, Buzău); *"We have some advantage when we have clients who will be future parents or have children already because they can empathize with our efforts"* (B.R., 40, Bucharest).

In terms of financing modalities and the role of state institutions in business development, entrepreneurial mothers prefer to use their own economies and self-finance themselves, believing that *"the Government has no contribution in supporting entrepreneurs, the bureaucracy is burdensome and the tax measures are inappropriate for starting a business: the taxes are too high... I really understand the mothers who want to work "underground" ... it is almost impossible to sustain your business, at least in the first year..."* (L.T., 40, Bacău); *"Although I filed financing requests, my projects were all rejected. The reason: reticence towards art as a prosperous business. The government has no contribution to our success... cannot count on it even for free advice..."* (M.A., 46, Bârlad); *"I prefer to call on specialists to teach me to grow my business because I do not trust government or European funds at all"* (E.B., 48, Miercurea Ciuc).

Although there is an upward trend towards supporting female entrepreneurship, the legislative measures are yet inexistent. The proposals of mothers related to changes in

legislation are varied and most of them concern the economic area: *"I propose the creation of a special legal form, with free of charge establishment and free of taxes for one year; it would be like a probationary year in which you can test the market, invest money in promotion, advertising, in events that make you known..."* (D.L., 29, Gherla); *"Mompreneurs could be supported by granting special credits, for example"* (P.O., 34, Constanta); *"Legislation that allows exposure of creations (products) without the imposition of a legal form would give a greater chance to increase the community of entrepreneur mothers"* (I.B., 55, Bucharest); *"A lower tax on profit would also be helpful"* (N.M., 31, Buzău); *"The state should provide us with the possibility to authorize us more easily, provide the option of submitting requests/ necessary documents online, provide free counseling for mothers, and some tax incentives for the first year of activity..."* (B.P., 36, Iași); *"First of all, I would try to boost entrepreneurship among mothers by providing benefits, cutting taxes, facilitating discussions between institutions in this sector because a state-supported mother could produce as much value as 10 employees"* (B.R., 40, Bucharest). An important step would be *"to set up NGOs to support mother entrepreneurs and address the legislative issues on their behalf"* (E.B., 48, Miercurea Ciuc).

By asking them to define themselves as mompreneurs, the participants in the interview defined mompreneurship as *"a fulfilled dream", "the proof that dreams come true", "the chance to work out of passion and to teach the children to be independent", "a challenge", "a quest of originality and perseverance", "a lifestyle", "a woman fulfilled on all plans", "the courage to do something for the family"*.

The recommendations of entrepreneurial mothers to future entrepreneurial mothers put emphasis on this quality of being a parent before being an entrepreneur: *"we shall not forget that children are more important than any business. A business can be replenished but the time we do not spend with our little ones cannot be recovered"* (N.I., 31, Alexandria), but also highlight the efforts that come with this dual role – *"At this moment, the mompreneurship for me is, on one hand, the joy to spend time with my little girl, and on the other hand, the many white nights of work. There are times when I'm thinking about giving up, just imagining myself knocking on a multinational company's door, but then I remember that this is the only way to have time for my little girl"* (B.P., 36, Iași).

B. The institutional support provided to the mompreneurs. Analysis of data obtained through interviews with representatives of some organizations in the field

For a complete picture on mompreneurship, we added a second field research to the study, having as interviewees with the representatives of some of the institutions involved in the development of this subgroup of entrepreneurs. The importance of this study is given by the objective, external perspective on the group of entrepreneurial mothers, exploring how their role in the society is seen from the outer world, as well as their importance in the creative sector. Also, the study aims to identify the measures taken in the Romanian space to encourage them.

The first part of the interview addressed to institutional representatives covered the subject of the increased interest in the creative industries and the factors that encourage women to start their businesses in this sector. Although Romania is still in its early stage of development of creative industries, *"changing the focus of funding programs from agriculture to creative industries has an important role in opening up to the international*

markets" (Start-Up Nation). Women are particularly encouraged to apply because these industries benefit them: *"the times when entrepreneurs were encouraged to have technical knowledge, especially from the real sciences have fallen, not that I imply that women are not good in this field, not at all - we have some great women engineers, hats off to them... but all of the business ideas from this sector were overwhelmed by heavy production, physical effort, and industrialization... Let's work with our heads as well"* (Chamber of Commerce). Among the factors that encourage women to build start-ups in the creative industries, the respondents named previous experience in the chosen domain, the desire to have a self-made career, the possibilities of self-financing, and the opportunity to call experienced consultants and trainers: *"Anyone can succeed, the market is prosperous, opportunities are everywhere... all we have to do, culturally speaking, is to get rid of this "we know them all" attitude and call on specialists when it's the case. If the Romanians learn to make long-term strategies and seek specialized help, a large part of the bankrupt companies will be saved"* (Level Up Vision). The major impediment, on the other hand, would be the *"tangled, confusing and unclear bureaucracy"* noted the representatives. Happy Moms Association draws attention to psychological factors such as the fear of failure, common among women who are prone to think this way regarding economical endeavors because of early socialization of their role in society.

The following questions explored the differences between female entrepreneurs and entrepreneurial mothers, and therefore the recognition and confirmation of the existence of this subgroup of female entrepreneurs in society. The representatives of the institutions take into consideration the statistics that show an *"increase in the birth rate, which leads to an increase in the number of mothers, which logically leads to a sabbatical period and implicitly to a professional reinvention and changes in the field of interests regarding the family/children versus the career relationship"* (Happy Moms). Also, the *"increased interest in documented parenting (reading blogs, books, attending courses and workshops) entails greater involvement of parents in family life, especially of mothers, who want to be with their children through their most important moments of their lives, to give them all the necessary attention for a better development, all reasons for which they are no longer interested in selling their time and energy to a corporation. Investing in a business that allows both time flexibility and consistent revenue seems the right choice for them at the moment"* (Level Up Vision).

The socio-demographic profile of mompreneurs as a distinct group of entrepreneurs, as described by the interviewed representatives, is the following: women aged 29-40, with higher education, urban, with a career of at least 5 years old, who already have a domain they can exploit in their own business development, who are open to the online environment for both business growth and promotional purposes (unlike men, for example), especially concerned with health, culture, parenting, well-being, interested either in developing businesses in the crafts area of handmade products creation in the north-west of the country, and in creating businesses in the service sector, in the southern area of Romania.

Exploring the phenomenon of mompreneurship in the Romanian space from the perspective of its institutionalization, we found that *"there are three tendencies among mompreneurs: (1) the copying, when the mothers stubbornly start a business without having an idea, a mission or purpose, just because they saw other mothers succeeding in the field; (2) the investments, a reckless action characteristic to mothers who just quit their*

corporate job, who have a certain amount of knowledge and a higher level of resources, which is why they engage in businesses that require large amounts of capital for initiation, risking large debts without market testing or experience in business management and (3) businesses that start from passions, from their own values, hobbies - these are the authentic ones who have a stable, organic growth" (Level Up Vision); "The phenomenon of mompreneurship is not yet recognized as such, but considering the avalanche of news, reports, programs, articles that have appeared in the past few months, it becomes more and more popular, shaping and strengthening the public image and the profile of the mompreneurs" (Happy Moms); "I think it is a more controversial phenomenon in urban areas, I believe that rural areas are completely lacking the culture of mompreneurship" (Chamber of Commerce); "Although not yet recognized as such, the advantage of this subgroup, from the client's perspective, is important - moms are regarded as responsible, empathetic, involved business people, warmer and nicer than traditional firms adopting a more masculine, colder culture and style. However, the size of the phenomenon is increasing, although there is greater coagulation in Cluj, signs of development begin to appear all over the country" (Level Up Vision).

The study addressed to representatives of the various institutions interested in the entrepreneurial mothers' group revealed an *intermediate* way of measuring business success: the ratio between economic profitability and familial success.

The involvement of institutions in the development of this phenomenon was a key point of this study. The questions were derived from a specific research objective, namely to identify the measures taken to support this subgroup of female entrepreneurs from a socio-cultural and economic point of view. Among the activities to facilitate the process of setting up a business by encouraging their entrepreneurial spirit, we found interesting initiatives, such as the launching of projects that prepare them for the competitive market. Take for example the *"Entrepreneurial Mothers School, which provides training, mentoring and advertising services. In 2 years, we grew 10 businesses and we have already started our third edition in March"* (Happy Moms-Business Mom). Also, organizing motivational conferences or networking sessions for mothers is an important aspect to their success: *"Our goal is to simplify the process by which anyone can access these funds. We provide information, support, counselors, financial support in our programs, mentoring, even moral support by encouraging ideas [...] we are open to everything new and mothers turn out to be a breath of fresh air in this business area"* (Start-Up Nation). Level Up Vision offers specialized business and branding consulting services, from documentation preparation to business or communication strategies: *"Our help contributes to organic business development through intervention on production and promotion, but that is not all that we do. Our goal is to leave a footprint. We are working on building the "Mamprenoare stamp" for the products so they can be easily recognized (inspired by the Made in Romania example), a symbol to draw attention to this subgroup of entrepreneurs dedicated to both businesses and children, who want to provide education and a prosperous environment for their families and communities [...] anyone can empathize with this, and we believe in the success of this project [...], but there is a need for consensus and clustering of groups to promote state support and interest to this phenomenon"* (Level Up Vision).

Conclusions

The purpose of this paper was to create a profile of mompreneurs and to identify the main characteristics of entrepreneur mothers from the creative industries in Romania, by investigating the motivations of starting a business, the favorable factors and the obstacles they've encountered, as well as the economic and social context in which they find themselves. The two studies we undertake had a complementary role in building a more comprehensive picture of the phenomenon: the self-portrait of entrepreneurial mothers (A), and the institutional support provided to mompreneurs (B).

The context of the research has amplified the need to study this phenomenon at an early stage. Although the number of women starting a business is much higher than any demographic group, and the number of mompreneurs is steadily increasing in the Romanian space, research on entrepreneurial mothers is still limited. Our study aims to identify the characteristics of entrepreneurial mothers as perceived inside and outside the group in order to outline the main aspects of the phenomenon, from the social and economic perspective, as well as from the cultural perspective. And, most importantly, prepare the ground for future research that targets this subgroup of female entrepreneurs.

The objectives of the first study aimed to create the self-portrait of entrepreneurial mothers by identifying the reasons for starting a business in the creative industries, the favorable factors and barriers to business development, by exploring the characteristics of the mother's status in relation to the launch of the business, as well as the opinions on government support, and the social and cultural context. In relation to the specific objectives, our study revealed that women face a higher degree of complexity when making career decisions after childbirth as they try to balance childcare activities with work and home care. Under the conditions of exercising these multiple roles, their limits translate into space and temporal limits, and the consequences of choices in social and economic constraints. For this reason, the influence of the socio-cultural context is also reflected in their motivations as it influences the values and attitudes of the mothers, their self-confidence, and ultimately affects their interests and their choices. The push and pull motivations and factors that have triggered a business launch in the creative industries lead to different perceptions of success. Our results show that mompreneurs' perceptions on entrepreneurial success derive from family background, from the values to which they adhere, their social experiences, and are tied to their motivations to start a business. As our lot was comprised by a small number of entrepreneurs to support our qualitative research, a quantitative analysis could help get more complex responses to the phenomenon.

One of the most important factors in starting a business is, according to our studies, the influence of family and society in general on women who want to open a business. A family that understands the economic value of entrepreneurship will encourage mothers to be interested in pursuing this endeavor. The community also has an important role to play in starting a business and in developing entrepreneurship by delivering benefits, feedback, inspiration, and networking among moms. However, entrepreneurial education must not be neglected. This has a special role to play in developing entrepreneurial skills and competences. The effectiveness of training programs, counseling or motivation conferences has been demonstrated by the results presented by the institutions participating in the research.

The perceived barriers are primarily related to financing, taxation, and bureaucracy. In the first phase, mompreneurs have a greater chance of developing their business in an informal context, free of taxes or administrative rules that limit the social capital needed to develop the business. Socio-cultural factors are important not only in motivating entrepreneurial mothers to start a business but also in removing the social and cultural barriers they face. These include the lack of market credibility, mentalities that do not support gender equality, and traditional customs that focus on the role of mothers for taking care of the family and home.

The second study has contributed to shaping a more comprehensive picture of entrepreneurial mothers by investigating the external points of view on this group of entrepreneurs, namely belonging to the representatives of the institutions that support mompreneurship. The specific objectives were to identify the main characteristics of the entrepreneurial mothers in the creative industries, to analyze the external factors that influence the entrepreneur mothers in starting a business and to identify the measures taken to support this subgroup of female entrepreneurs. Unrecognizing the group of mompreneurs as such, underestimating them or canceling their entrepreneurial qualities because of the “mother” status they have, are attitudes often encountered by entrepreneur mothers. However, the growing interest of the institutions supporting this group of entrepreneurs, their involvement in promoting the image of mompreneurs, encouraging and facilitating actions aimed at educating mothers to start their businesses redirects the socio-cultural discourse and economic goals. Moreover, the media and the educational system play a particularly important role in creating the image of entrepreneurial mothers and can avoid the formation of negative attitudes in the future.

Although the group of mompreneurs is part of the homogeneous group of Romanian entrepreneurs, our study revealed that the neutral reporting of the state to this subgroup of entrepreneurs is not beneficial. Decision makers and experts should consider evaluating alternative policies for tolling small and medium businesses, modifying the design of an application for funding projects, as well as providing technical support and ensuring a healthy business environment based on equal opportunities. National policies play an important role in business development and have a critical role in facilitating success or in business failure. Under the obsolete legislation and taxation of our country, an interesting subject to study arises: how would the Romanian entrepreneurial mothers in the diaspora relate to entrepreneurship in the creative industries, eliminating the economic or socio-cultural barriers specific to the countries with a lower tradition in entrepreneurship, such as Romania. Moreover, as the socio-demographic data presented by the representatives of the institutions that participated in the study reveal, the mompreneurs are mainly from the urban area. It would be interesting to study why this phenomenon does not spread in rural areas, especially that as we have seen in previous studies, mother's qualities can greatly prepare entrepreneurial skills.

The complementarity of the studies has allowed a thorough analysis of the phenomenon through a comparative analysis that complemented the image of entrepreneurial mothers, first as they perceive and describe themselves, with the understanding of the motivations and the correlation between the expectations and fulfillment regarding

their double role, and secondly as viewed by the representatives of the institutions in the field from outside the group.

Thus, after analyzing the collected data, we aimed a comparative interpretation from the two undertaken studies, delineating the main characteristics of the entrepreneurial mothers from the creative industries in the Romanian space. This comparative analysis served as a base for outlining the profile of the mompreneurs as it resulted from the research. The first step was to delimit this subgroup of entrepreneurs through socio-demographic characteristics: 25-40-years-old, urban area provenience, generally women with higher education and careers in diverse areas - banking, human resources, medical, advertising, marketing, psychology etc. This information lead to a broader area of interests and skills of the mothers: professional experience in managing clients, understanding the needs in the sectors they have worked in, orientation towards the creative industries in terms of increased interest in health, culture, parenting, wellbeing, online marketing. Regarding the specifics of their business, the studies show that mompreneurs from Transylvanian and northwestern parts of the country are more focused on the production businesses: handicrafts, handmade products, Romanian products, personalized products etc., while those located in the southern area prefer businesses in the services sector: therapy, consultancy, various services focused on child development or parenting (for example, financial parenting coaching or baby sleeping counseling), event planning, make-up or styling courses etc. Next, we analyzed the phenomenon of mompreneurship from the perspective of the lifestyle assumed by the mothers, the psychological, emotional and behavioral characteristics deriving from this status. In this context, entrepreneurial mothers describe *mompreneurship as a lifestyle, a state of freedom they are fortunate to have* (compared to past generations), a phenomenon that emphasizes the *family life-professional development balance, a dream came true, an accomplished woman on all levels, a phenomenon with a growing network, the opportunity to do what you want, or the best choice for mothers*.

This study aims, on one hand, to create a fresh theoretical framework, both by creating original correlations between the studied basic concepts and by implementing new ways of analyzing this phenomenon from a social, cultural, economic point of view. On the other hand, this paper initiates the bases for future studies on mompreneurship through insights and results. Quantitative studies at the national and European level are expected to be undertaken in order to analyze, validate or extend our observations. Another purpose of this study is to draw the attention of authorities in the field to encourage and support the businesses belonging to mothers in the creative industries, taking into account the results of our study when creating new public policies for childcare support, maternity leave, or when implementing new financial regulations over small and medium enterprises.

ROMANIAN PUBLISHING INDUSTRY – DEAD-END OR CROSSROAD. SOME NUMBERS AND POINTS OF VIEW

Bogdan HRIB

Tritonic Publishing Group

5 Coacăzilor St., Sector 2, 022651, Bucharest, Romania

bohrib@gmail.com

Abstract. *Culture and, above all, cultural industries are the first to be affected by economic crises and changing the taste of the public. The book market in Romania has always been at the edge of the interest of state people, either by disinterest or through regulations that hinder the development of the domain. Do you need Romanian authors alive? Or only translations? "Bestseller" - a noun that came worldwide directly from English, is the magic word of the book industry. For some Romanian publishers, of course, the bestseller means the first print run of 100 copies, for others, large numbers mean four or five zero at the end. The development of digital printing has allowed books to be printed in small prints at reasonable prices for any customer, whether publishing house or individual (independent author). The main question both authors and readers ask is whether we still need publishers. There are already commercial companies in Romania that provide editorial services on demand. On the Romanian market, some important actors in online book distribution are struggling, with three of them having a top position, detached from the rest of the platoon, made up of smaller companies, the sites of important bookstore networks, or even the publisher's personal websites. By comparing the statistics provided by the Cultural Consumption Barometer and those of the main market actors (publishers and book fairs) for the Romanian side to those of other European and international markets (from the specialized publications) we will find the situation of the market of the book in Romania. I will try to identify the potential problems and potential solutions for stabilizing and eventually developing the book industry. Between the lack of interest in reading and the development of functional illiteracy at an extreme and the rapid technological development at the other extreme, the Romanian book market is still in the search for a faithful public and methods to approach the written text no matter how it is presented - printed book or e-book and regardless of how it is published or distributed.*

Keywords: *Publishing industry; Publishers; Bookstores; Library; Print-run; Readers, Authors.*

Introduction

Culture and, above all, cultural industries are the first to be affected by economic crises and changing the taste of the public. The book market in Romania has always been at the edge of the interest of state people, either by disinterest or through regulations that hinder the development of the domain. A simple example would be the Law of the book that was still discussed without any finalization.

Massive translations have not been able to support the industry themselves by promoting in-flight package with manuscripts. The presence of a name on the cover and just so, sublimely induced the idea of a character located somewhere far, inaccessible, eventually disappeared from the real world.

The lack of a coherent policy that encourages Romanian authors - both classics and living - those who could have acted directly as actors in promoting the sector generated an enormous opaque curtain between authors and readers. I have often heard the phrase - *We still have Romanian authors in life?*, and the answer through the physical presence of the authors has not yet succeeded in convincing the Romanian public that it can be written at international standards and in Romania.

Where and what is the market today? A few numbers

Romania currently has about 12,000 registered publishing houses, but only about 1000 are active on the market (WallStreet.ro, 2018) and 500 publishers participate (Gaudeamus.ro, 2017) in one of the main book fairs in the country - Gaudeamus International (in Bucharest each November). So in the summer at Bookfest. Romania currently owns about 160 physical bookstores and less than a thousand public libraries: in addition to 40 county-libraries, town and village libraries mostly do not have funds to purchase the book.

The count of titles published in Romania is based on the ISBN code-numbers given by the publishers (received from National Library of Romania). According to this statistics, there are about 50,000 new titles each year.

The development of digital printing has allowed books to be printed in small prints at reasonable prices for any customer, whether publishing house or individual (independent author). The Friendship Pattern - a form of self-publishing of pride has developed tremendously over the last 4 years, so anyone can publish about 1,000 lei, 100 copies of a volume of about 100 pages, with materials of good quality, then send them to friends. About the quality of the text - story, style, grammatical rules - no one remembers anything because the pattern has been democratized and accessible.

What is a bestseller?

"Bestseller" - a noun that came worldwide directly from English, is the magic word of the book industry. For some Romanian publishers, of course, the bestseller means the first print run of 100 copies, for others large numbers means four or five zero at the end. There is no objective definition of the term, its relativity being generated by each national or linguistic market in part.

But a book sold well or extraordinary is a good book?

Frederic Rouvillois (2013) in the volume "A History of the Bestseller" quotes Carlos Ruiz Zafon who believes that "success is a guarantee of quality"; so a bestseller is a "good book". But it continues: "In reality, literary success and value - quality and quantity - are not a deflection in binding relations. Very large books were resounding failures, while others, including the incontestable masterpieces of the human spirit, have glorified their very first appearance, just like some kind of easy or two-talented novel about which, retrospectively, we ask how they have he could have liked so many people. A best seller can be a sublime book - and so good a mediocre or even exuberant: everything is possible. In terms of quality, success means nothing. So if we want to define the bestseller, we need other criteria: the number (copies sold), the time (of which success

needed to take place) and the place (the bestseller's history showing that success has always ignored the borders)." (Rouvillois, 2013, pp.13-14).

With deep frustration I would add: the language (in which the manuscript was written and the first edition of the book appeared). Many times the theoreticians of the world book industry have analyzed situations, have written and published articles with volumes in high-circulation languages: French, English, German, Spanish, Italian, Russian, the languages of the great empires of the Middle Ages, The Renaissance, the Seasons of the Light and the Technological Revolution. In a still low-lived and somewhat illiterate Europe, at the edge of the empires, the small number of readers could not hold a consistent book market until the second half of the nineteenth century.

Brief history of the bestseller

Specialists believe that the appearance of *The Pilgrim's Progress*, signed by John Bunyan, in 1676, was one of the first bestsellers in English in history (Owens, 2003, p.xiii): "The book has never been exhausted. Numerous editions have been published and translated into more than two hundred languages."

Let's not forget that at that time the pattern was made exclusively by hand and implicitly the time required for printing a volume was particularly long. Rouvillois states: "More than circulation, the sales figure is impossible to calculate precisely: what shows the success of a book (at that time authors note.) is the number of editions, possibly translation. That's why, for some, "the first bestseller of world literature" was a book that was taken out on January 16, 1605 in just a few hundred copies, in Juan de la Cuesta's *Madrigal Printing: Don Quixote* by Miguel de Cervantes. And that's because "ingenious Hidalgo" generates a general enthusiasm, first in Spain and Portugal, then across Europe." (Rouvillois, 2013, p.32)

Nowadays situation in Romania and worldwide

The Romanian market

On June 11, 2018, Afrodita Cicovschi publishes an article (on the *Adevărul* blog) titled: "The Romanians are returning to reading. The book market reaches the maximum of the last 7 years." Without completely sharing the author's enthusiasm, especially since the text appeared at the same time as Bookfest 2018, in the new pavilions at RomExpo and the figures seem slightly brushed, I would choose two quotes that offer an up-to-date picture of the Romanian publishing industry (Adevarul.ro, 2018):

"According to KeysFin estimates, the turnover of publishers and book traders in Romania will exceed the level of 1.11 billion lei this year, by 16.2% above the 2012 level. Against the backdrop of business consolidation, publishers and book sellers have optimized their spending, so the sector's profits have doubled from 2012 to the present, from 51.3 million lei to over 100 million lei, a figure projected for the evolution in 2017. Business Radiography in this area shows that the number of companies has remained constant during this period, around 1000 publishers and 350 merchants. (...)"

"Top of the most profitable book business (...) The top book editors are headed by the Art Publishing Group, with a turnover of 38.2 million lei, followed by Group Media Litera SRL (26.6 million lei), Tarsago Romania SRL (25.3 million lei), POLIROM SA (23 million lei), Humanitas SA (19.3 million lei) and Lotus Publishing SRL (17.2 million lei)."

KeysFin data show that the top 10 players in the market achieved 36% of total turnover in the publishing market, estimated in 2016 at 585.3 million lei. In the bookstores' top, the most important player is Direct Client Services SRL (Cărturești), whose turnover of 87.1 million lei accounts for almost one third of the turnover of book traders in Romania. The top is completed by the Bookstores Company Bucharest SA (45.6 million lei), Blor Retail SA (Diverta) (45.6 million lei), Libris SRL (27.4 million lei), SedcomLibris SA (19.7 million lei), One Distribution Company SRL (18.2 million lei) and Humanitas Bookstores SA (17.5 million lei). "

Some comments are needed regarding the quotes above. The first would be to mix publishing publishers with books and especially those who only trade editorial products. A simple example: Lotus Publishing appears in some materials as a glossy magazine editor, and 11 ebooks are all on the eMag website (eMag.ro, 2018), all edited abroad and in foreign languages. You will also have a similar surprise if you come to Tarsago's website (Tarsagomediagroup.com, 2018). Which means that if we remove firms that import magazines and books or complementary products (cars and trains or others) for sale at kiosks, their own national book production is much smaller. However, the above turnover in the euro is about 120 million. My estimation, of course empirical, proposes a figure of approximately 80-90 million euros for the Romanian book production.

Another issue that needs to be clarified is that of sales of bookstore chains. Let's not forget that there are all sorts of handicrafts, teas, and there are terraces where you can eat - I am not at risk of saying that they are managed by the same companies. There is also a lot of imported goods. In addition, most bookstore networks sell stationery and related products - gifts, crafts, drawing and painting materials, leather goods, DVDs, etc. So I think we cannot have a clear picture of the book market in Romania.

Another statement makes me nervous in the text above. The number of players on the market estimated by analysts at KeysFin at approximately 1,000 publishers. The figure seems to be removed from my hat because it does not even approach the figure advanced by, for example, the Gaudeamus Book Fair (one of the most important or even the most important editorial event in Romania) - 300 participants or the one offered by the National Library of Romania - a much larger figure we will come back to. In conclusion, the data is quite unclear and unsafe.

However, for a picture of the place that the book occupies in today's Romanian society see table 1 presenting information from the Cultural Consumption Barometer (2017, 2018, p.185)

Table 1. Frequency of reading in Romania

<i>In the past 12 months, how often have you read books (generally)?</i>	
The national sample	The sample on Bucharest
- 42% never; - 27% less; - 10% several times a year; - 9% monthly; - 7% weekly; - 4% daily.	- 29% never; - 29% less; - 14% a few times a year; - 13% monthly; - 11% per week; - 3% daily.

As expected, book use in urban areas is much higher, the category never fluctuates from 29% in the national sample to 29% in the Bucharest sample. However, if we collect *the*

professionals - those who read weekly and daily - the differences are not very high: 11% at national level compared to 14% in Bucharest. Unfortunately, the research does not specify the relationship between the fiction book and the non-fiction book, because I have often encountered reputable readers who say openly and without remorse: *Dear, I have no time to read novels or poems, I read just what I need for school (or job).*

The other markets

According to *Statista.com*, in 2015, the main players on the book market are: the US with 25.99 billion euros, followed by China, Germany, United Kingdom and France.

Figure 1. Top book markets. Source: Statista, 2015

After *Publishing Perspectives*, the material provided by the StatShot Annual Report - announces for the year 2017 a figure of \$ 26.2 billion for 2.7 units (children's paper or e-products) traded, a figure continuing a slight trend downward trend of the last five years - from \$ 27.07 billion in 2013, for the US Publishing Market (Anderson, 2018). A slight decrease in adult fiction and a significant increase - 4.4% for adolescent fiction (YA). A last observation: the paperback volumes (on paper!) Dominate all categories - over 1 billion units sold.

On another scale, in Europe, we chose to present the figures from Lithuania after the latest material made available by the officials of that country: The Latvian Book Market. (The Latvian Book Market, 2018, pp. 6-7)

A 2004 EU member country with a population of 1,931 million (less than Bucharest!) presents the following data:

- the number of publishers (who publish at least one title per year): 475,
- new titles per year: 2146,
- average print run for a title: 1263 copies,
- average book price sold in bookstores: 12.07 euro.

And two other important information:

- 12% VAT for books and 21% for electronic publications;
- 150 bookstores and 1671 libraries (impressive figure for a country with 2 million inhabitants)

Finally, the percentage of people who read at least one book a year: 57%.

Motivations associated with the book industry

The most important questions that the book industry goes through today from authors to publishers and then to readers are:

Why do Romanians write so much?

Why do Romanians read very little?

Why do Romanians read more translated Foreign Books?

Why do I read the Romanian authors?

May I earn enough money for leaving from rights of published books?

Let's see some examples

A top set by Forbes Romania in 2011 (adevarul.ro, 2011):

1. Mircea Cărtărescu;
2. Gabriel Liiceanu;
3. D.R. Popescu;
4. Andrei Pleșu;
5. Nicolae Breban;
6. Neagu Djuvara
7. Augustin Buzura
8. Nicolae Manolescu
9. Dinu Sararu
10. Radu Paraschivescu

Since then, some places may be slightly modified because recent years have brought literature closer to readers. Especially after coming back in recent years. I am convinced that the volumes of Professor Lucian Boia could bring him to this top. Without joining them I want to be content about the content of the writings, and without any comment, I think of at least a few other names that appear (at least from the editors and librarians' declarations) to come to the forefront: the volumes of Irina Binder Fluturi, Butterflies), then the diptych ... Suffer by Andrei Ciobanu, the historical thrillers signed by Igor Bergler, the volumes of Mr. President Iohannis, and perhaps there would be other examples. All report figures in the tens of thousands of copies. Personally, it seems to me that some of the figures are much swollen, but I have no argument to support this statement.

There may be some people - 20 or 30, or even 50 who have earned a lot from writing. A comparison with the Western market would be pointless.

Therefore, all the others who publish – we are mainly referring to fiction - hope in a miraculous enrichment through immense circulation or just aspire to a local recognition among friends, colleagues, concitadins? We incline to believe that any creator has a very well developed ego, but enrichment depends on many more factors that are not and cannot be under the personal control of the creator. Many of them are in the editor's choice.

Solutions for a new type of market

The main question both authors and readers ask is whether we still need publishers. There are already commercial companies in Romania that provide editorial services on demand. An example is the Berg Publishing House (edituraberg.ro, 2018):

"PUBLIC

You wrote a book, and the friends who read it were impressed. It is time to publish the manuscript; we are here to support you.

In partnership with www.serviciieditoriale.ro, a registered trademark of the BERG Publishing House, we have prepared for you a set of rules that you are going to follow to ease the work process and the duration of your book.

Your book can be done in 4 easy steps. "

Of course, everyone has the right to manage their business as they think, and we have all the respect for Berg's leadership. The site is clear, simple, efficient, easy to understand for everyone. Our question is whether an author keeps sticking to the name of a firm that publishes the author's money? Or if the author still needs a publishing house? Or even simpler if you are turning to self-publishing - because ISBN code numbers can be released to individuals, so you can publish your own work yourself.

Editorial services (as Berg presents):

- Drafting / proofreading;
- Pagination (layout);
- Cover (cover);
- Publishing (I would have said the necessary publishing operations here, many of them: from the simple ISBN to the printing itself.)

The new paradigm: New media and the book market. Integrated LIBRIS model

On the Romanian market, some important actors in online book distribution are struggling, with three of them having a top position, detached from the rest of the platoon, made up of smaller companies, the sites of important bookstore networks, or even the publisher's personal websites. They are: elefant.ro, libris.ro and librărie.net. About one of them the article of August 10, 2018, signed by Ovidiu Vrânceanu (2017) in BizBrasov:

"Libris.ro, the largest online book retailer in Romania, grew by 40% in the first six months of this year and registered a turnover of 18.3 million lei.

The positive dynamics is due to the increase in visitors' conversion and return rates on the site, as well as the market and interest in popular or expected titles, such as Irina Binder or Sapiens, Short History of Humankind (Yuval Noah Harari).

The best-selling product categories are Fiction, Personal Development and Children's Books, which together generate over 80% of sales on Libris.ro. An interesting dynamic was also played by the books in Practical Psychology (+ 76%) and Child Growth (+ 67%).

Romanians' interest in the printed book is rising due to the increasing number of titles and promotional mechanisms that help the information to spread rapidly to numerous and well targeted audiences. For Libris.ro it was a very interesting first half of the year, we registered increases in all categories of books (...), "says Laura Țeposu, Development Director Libris.ro.

(...) Traffic from mobile devices has accounted for 60% of all visits to Libris.ro and generates 45% of sales, an increase of almost 80% compared to the first half of the previous year. The cities where most orders are placed are Bucharest, Cluj, Timisoara, Iasi, Brasov, Constanta, Ploiesti, Oradea and Craiova. In the first six months of this year, Libris.ro has sent over 250,000 orders to readers across the country. The average value

of an order placed on Libris.ro increased by 9% compared to the same period of 2017, up to the threshold of 72 lei.

(...) The first half of this year was marked by investments in three strategic directions: the new Libris deposit, optimization of site conversions and improved customer and visitor experience, as well as the #RespectYourself education campaign. Give your reading time, which encourages reading and presents reading as a form of respect for one's own person. "

It is important to note that Libris is not an exclusively online actor, nor has he emerged from nothing. One of the most important bookstores in Brasov - Șt. O. Joseph, excellent positioned on Muresenilor St., wore the first brand of Libris. Then there was a spring book fair that had already 15 editions and the Festival of Books and Music (summer in the Council Square) already has 10 editions. The Libris Cultural Association that organizes them also organizes a folk and a poetry festival. But Libris is stretching more and more because there is already a Libris Editorial with a production of several titles per year and partnerships or participations in Local Book Fairs (e.g. Alba - Alba Transilvania, together with the county library) or the Festival SIMFEST Târgu Mureș (documentary film and independent television).

Although I admit that I do not like monopoly politics and Libris Editorial's production seems rather heterogeneous, however, Libris is a serious and extremely powerful player in the entire book market. Incorporating all these activities under one big hat has the chance to harmonize the potentially critical moments of one or other of the components as needed.

Brief conclusion

Between the lack of interest in reading and the development of functional illiteracy at an extreme and the rapid technological development at the other extreme, the Romanian book market is still in the search for a faithful public and methods to approach the written text no matter how it is presented - printed book or e-book and regardless of how it is published or distributed. Target audience the main issue of the book market, need to read - remains an undisclosed puzzle in 2018.

Abstract. *Technology is rapidly changing business models in the cultural-creative sectors, challenging the way availability, marketing and revenues work. From a business innovation perspective, the history of music distribution has always followed the trend of making it accessible but also profitable. Creative breakthroughs in software technology have made it possible for intermediaries to distribute music to huge crowds all over the world. The emergence of on-demand streaming platforms such as Spotify or Deezer has transformed the idea of purchasing music from a pay-for-song model to a payed subscription model, causing controversies on the sensitive topic of intellectual property rights and royalty payments. However, the benefits of streaming music using these platforms translate in increased usage and therefore, higher revenues on scale. This paper offers an overview of the innovative business models of the online streaming music industry, concentrating on the unique added value new platforms offer, namely transforming unpaid consumption into payed subscription. We start with a short background of the major developments of music as an art, from an elitist attribute to a large-scale available service. A short review of the innovations in music distribution in the last centuries is performed in order to make it possible to differentiate between the major services existing today. For the applied section of this paper, we look at the increased usage of interactive streaming platforms such as Sirius XM, Pandora and Spotify, and correlate the data with their global revenues. Authors also look at the data regarding music piracy in order to assess if there is a negative impact of the on-demand streaming platforms on piracy practices. Conclusions are drawn regarding the impact of on-demand streaming platforms on overall usage, with a focus on the need to further develop business models that make the music industry both profitable and sustainable in the long run while simultaneously allowing for world-wide accessibility.*

Keywords: *creative sectors; music industry; Spotify; Deezer; business innovation.*

Introduction

The history of music and especially music distribution is maybe one of the most fascinating stories there are. With historians estimating its appearance 35,000 years ago (Wilford, 2009), music has become an essential part of people's major life events in ancient Greece, and its primitive recording using reproduction instructions dates back to 1200 B.C in the Babylonian era (West, 1994). The so-called "modern tradition" of listening to live music has its origins in the European Middle Ages, where pipe organs were first used in Churches for Gregorian chants, and where later classical music developed (Zantal-Wiener, 2017). The idea of consuming music independently from an event and without somebody live-playing it appeared with Thomas Edison's 1877 invention of the phonograph, which made it possible to record music (Edison, 1878). This is when the original transformation of music from service to product first took place. Around 1890, once phonograph parlours appear, wealthy people could pay money to listen to a recorded-song, using a primitive juke box-like machine. Once the first record shops appear in the UK so did the practice of signing artists to record label companies, and thus, in 1909 the idea that royalties from record sales should be paid not to the performer, but to the music writer and publisher of the song (United States Congress, 1909), a practice used until today in the music distribution industry. Between 1914-1921 record sales had witnessed a 100% increase only to then fall dramatically once radio broadcasting of music had started (Morton, 1964). Radio already meant the return of music to the state of service, while continuing to be a product as well, once the vinyl became popular, followed by cassettes and compact discs. Radio never went extinct although it has gone through periods of decline in popularity. Radio kept coming back by leveraging the desire of consumers to discover and distribute new music, at first in analogue format, then digitally, giving people the advantage of not having to deal with storage issues, either in physical form for traditional media or in digital form for downloaded content. Pandora was born, combining the benefits of traditional radio with the personalisation features enabled by digital software technologies. The most innovative feature of internet radio was surely personalization and the possibility to use smart algorithms to figure out what each customer might enjoy listening to (Zantal-Wiener, 2017). Monetizing this "free" business model was easy, as ads were introduced in-between songs which led to the development of a customer base paying for premium ad-free accounts. What Pandora lacked, and it was mostly due to its marketing as a for-discovery platform, was the possibility to look and browse for a specific song. And this is what made room for the innovations brought forth firstly by the likes of iTunes or Google Play Music which offered the possibility to quickly look for songs and listen to them in exchange for money. The bigger innovation however came from Spotify, a platform released in 2008 which outranked most its competitors including Pandora (Geddes, 2016).

Based on this condensed history of music distribution we can identify a few major patterns. The first one is that music started as a service only to later transform into a product, as a result of the advancement of recording technology. Later on, new technologies have made it possible to stream music and develop new business models based on the sale of a service or an experience and not necessarily a music product. However, music as a product came back in the shape of iTunes to again switch to be distributed as a service using Spotify or Deezer. Most of these changes happened simultaneously and they did not exclude each other. Since old-fashioned vinyls have never gone extinct because they are still produced and bought by collectors and fans,

there is no hint that music's future is based on a service-type model. The other important aspect to be acknowledged is that the major breakthroughs in the music distribution industry were accompanied by innovative business models. We've started from paying the performer of the live music to paying music publishing houses for distributing song sheets (Voice, 2014), followed by decades of paying royalties to song writers and publishers either through national societies of composers, authors and publishers in the radio era or, paying directly to the music rights holders in the Spotify era.

Understanding the business models behind streaming services

Before discussing the strengths, benefits and weaknesses of the different business models that are used in today's music distribution industry, one should look at the rationale behind the most used services within the field. The most popular streaming services can be divided in three main categories (Marshall, 2015): webcasting or streaming radio, locker services and on-demand.

The first category ranges from traditional radio services that have moved to the virtual space to online-designated less personalized stations that can offer the possibility to choose specific genres or artists - such as SiriusXM - (What is SiriusXm?, 2018) to finely and thoroughly personalized content - such as Pandora, a platform available in the US only, which uses the Music Genome Project adding up to 450 musical attributes to each song (About The Music Genome Project®, 2018). As mentioned earlier in this paper, Pandora does not allow users to choose a specific song, which means it's non-interactive (Marshall, 2015).

Figure 1. Number of Pandora's active users from 2009 to 2017 (in millions)

Figure 1 shows the evolution in the number of active users on Pandora. Although a 6 million decrease in active users has been recorded between 2015 and 2017, the continuous increase in revenues in the same period (Figure 2) suggests a growing interest in their paid services and an impressive transformation of free riders into

paying subscribers. Financing Pandora is mostly done through advertising – for the free accounts – and through paid subscriptions of \$9.99/month/user.

Figure 2. Pandora's revenue from 2006 to 2017, by source (in million U.S. dollars)

The latest announcement regarding the acquisition of Pandora by SiriusXM (SiriusXM, 2018) for \$3.5 billion could create the biggest audio entertainment company, outranking YouTube and competing with owned music in the share of audio time that American adults spend on different sources (Figure 3).

Figure 3. Share of audio time American adults spend with different content sources

The second type of streaming services described by Marshall (2015) are the so-called locker services provided by either iTunes, Google Play Music, Amazon etc. Although the

main innovation provided by these platforms is ease of access, as suggested in Figure 3, their share in time and usage is relatively small. This can be explained by the average costs of downloading a song which in 2011 was around \$1.29/song (Dediu, 2011). The third category, and the main focus of our paper, is made up of on-demand streaming services. Similarly to Pandora, they offer personalised content but also the possibility to choose what music gets played. Interactive platforms such as Spotify or Deezer have gained a lot of popularity especially because they have entered the global market, while Pandora and SiriusXM remained US-only. Spotify is funded through both advertising and premium accounts/subscriptions and the latter surprisingly outweighs the former (Figure 4).

Figure 4. Spotify's revenues from 2012 to 2017, by segment (in million euros)

One of the smart business decisions undertaken by Spotify has been to establish different subscription prices for countries worldwide. Although available in 65 countries on all continents (Spotify, 2018), prices differ and are most-likely adjusted to the purchasing power of the individuals. Hence, prices for premium subscriptions range from \$2.42 in Indonesia to \$3.44 in the Philippines and from \$5.78 in Romania to \$11.18 in Sweden and \$9.99 in the USA (Peoples, 2018; Singers, 2014). Furthermore, for some countries such as Thailand a 1-day subscription can also be purchased (Peoples, 2018). As features, Spotify builds on existing technology, combining both the attributes of personalized for-discovery Pandora-like webcasting services through its song radio function, with the iTunes ease of access for specific artists and songs, all at reduced prices.

Literature review

One of the most discussed topics in the field of streaming research relates to the impact new streaming platforms have on sales. Derouzos' (2004) study demonstrates that radio airplay has a positive effect on music sales. Aguiar and Waldogel's (2015) study suggests that the Spotify and Pandora business models resemble terrestrial airplay stations as a result of their musical discovery feature. However, we would note that while terrestrial radio stations might determine the consumer's desire to buy an album after hearing it

on the radio, a digital app such as Spotify might influence the consumer to replay the song, which is something that changes the entire logic of their argument. Kretschmer and Peukert (2014) are arguing that the presence of an artist or band on YouTube increases the sales of their music, while McBride (2015) finds that sales decrease in areas where certain songs are not played. This can be explained using the marketing factor. If the majority of consumers listen to their music using a certain distributing source, then, the absence of an artist – especially a debutant – from that platform translates to lower reach and thus, lower sales.

Moving on to the impact of streaming on revenue, Aguiar and Waldfogel (2015, p.7) argue that:

„While sales stimulation is sufficient to demonstrate a positive impact of streaming on revenue, a negative impact of streaming on permanent sales - sales displacement - is not sufficient to demonstrate that streaming reduces revenue. Because Internet radio services pay rights holders for streams, the effect of streaming on revenue depends on the rate of sales displacement.”

From this perspective, streaming platforms that are appealing legal alternatives to piracy can incentivise consumers to pay the subscription and therefore, contribute to the artist's compensation. However, their conclusion is that while Spotify decreases piracy and increases revenues, the results are in fact offset through the decreases of sale-acquired revenues (Aguiar & Waldfogel, 2015). In our opinion, the results of the study don't imply a correlation between the two, as there are other factors affecting the sale of permanent downloads, such as the existence of more cost-effective alternatives that also allow for the discovery of less-known artists.

The controversy regarding on-demand platforms revolves around the problem of royalties and it involves the argument of decreased sales of records. Spotify's response to the controversy was that the royalties artists receive from Spotify are in accordance with the contract they have signed with their respective record labels (Marshall, 2015). Similarly to radio stations, Spotify pays distributors and not artists (Stahl, 2013). The problem in this case is not the relationship between the artist and Spotify but between the artist and their distributor/producer.

A model for understanding revenue streams

A great deal of data is available, in particular to service providers like Spotify, Deezer, Apple or Google which can be used to assess the transfer of customers, and revenue, between companies and distribution channels in general. The following is a description of a model used to determine potential revenues within the music industry more accurately. While our model is still susceptible to errors generated by overly-inflated estimates regarding losses to piracy that are usually circulated by recording industry associations, artists, and record labels alike, due to its usability at the level of individual artists we hope it will generate valuable results for business decision makers in the field. On an industry-wide level it has the potential to shed some light on whether or not actors in the music industry are behaving efficiently and intelligently by pursuing their best interests.

Methodology

The foundation of our model was a price differentiation mechanism aimed at maximising revenue on the global market. One such model is already employed in practice by Spotify, as mentioned previously, by charging different amounts for the same service depending on the country of residence of the customer. Rather than attempting to apply price optimisation to the prices of a music distribution service that already uses differential pricing, we looked at price differentiation and optimisation from the point of view of the music creators themselves. Doing this meant that we could not treat music as a homogeneous product, as Spotify does, instead we would also have to account for product differentiation. A similar model covering some of the aspects required for this kind of differentiation has already been developed by Gallego and Wang (2014) in their work on multiproduct price optimization and product-differentiated price sensitivities.

For the purpose of our study we assume that the quantity of music (Q_M) purchased globally is the result of a function of price and convenience, where convenience is not a coefficient but a score that can be used for ranking sales channels.

$$Q_M = f(\text{price}, \text{convenience})$$

By using a very simple function based on supply and demand we chose to express this function as:

$$Q_M = (1 - NRP) \times C \div p$$

where:

NRP – natural rate of piracy

C – convenience score

p – price

The music revenues generated by a particular artist are the sum of revenues obtained through the various distribution channels.

$$R_M = \sum_{i=1}^n Qc_i \times pc_i$$

where:

Qc_i = quantity sold through channel i

pc_i = price for channel i

By substituting quantity from the first formula into the second we can single out the convenience score as the determining factor for revenues across sales channels.

$$R_M = (1 - NRP) \times \sum_{i=1}^n C_i$$

As a corollary of the above we can also deduce that the convenience score should be computed as the amount of revenues generated by an artist from a particular channel weighted against the natural rate of piracy (NRP). The resulting formula can be used bidirectionally, to compute potential revenues and convenience scores based on actual revenues, depending on which data we have at our disposal first.

$$C_c = \frac{R_c}{(1 - NRP)}$$

where:

$$C_c = \text{Channel Convenience Score}$$
$$R_c = \text{Channel Revenues}$$

The formula in this form is only applicable to the sales of an individual artist due to product differentiation constraints.

The key component of our model, one whose computation proved to be extremely problematic, is the natural rate of piracy (NRP). We initially tried to determine the NRP based on a behavioural model (Gopal et al., 2009). This approach did not yield reliable results due to the lack of data on the matter and the high level of uncertainty with regards to the accuracy of the available data. People are simply inclined to misrepresent their behaviour when they are polled with regards to their potential illegal activities. The NRP was computed as a global coefficient based on data from the IFPI (2000, 2016) and RIAA (2015, 2016, 2017, 2018). To counter potential bias, the data was adjusted based on observations detailed in Smith and Telang (2012), and, in particular, in Andersen and Frenz (2010) and Hammond (2014).

The final NRP computation was done by using data points regarding global sales volume (GSV), average song price across all formats (ASP), and piracy rates (according to RIAA and IFPI) between 1999 and 2018. Our linear model provided us with a marginal rate of increase in sales, in relation to decreases in price, of 1.225. As part of our preliminary simulations we chose to estimate NRP for an ASP of \$0.00001, where NRP was 9.75%, and for an ASP of \$0.000001, in which case NRP was 8.91%. The minimum value of the rate of piracy was 8.9% which is the NRP we have used for the remainder of this research.

Finally, all components of the model benefit from increased accuracy when applied to a multitude of artists, as some factors, like the natural rate of piracy (NRP), are expected to fall within a set range, close to the one estimated for the entire industry above, even when they are computed for individuals.

Results and discussion

Through the development process of our methodology we were able to conclude that any determination of global revenue potential is highly dependent on the natural rate of piracy (NRP), or, in other words, how much music piracy would still occur if all music could be obtained for a price approaching \$0.

According to the IFPI Music Consumer Insight Report (2016) 35% of Internet users access unlicensed music content while 71% of Internet users actively consume licensed music other than radio. These figures are particularly interesting if we compare the percentages to the IFPI Music Piracy Report (2000) in which it was stated that “one in three recordings worldwide is pirate”. Although the language used by the IFPI is still strong and the percentages in the two studies set 15 years apart are similar it is important to realise that they show a completely different situation. Music piracy these days is declining continuously due to the proliferation of on demand streaming services. 35% of Internet users accessing unlicensed music translates to as little as 6% and no more than 18% of all music globally being pirated. That is a 50% decrease in piracy compared to the year 2000 even under the worst-case scenario.

To eliminate alternative explanations for these incredible developments in the music industry we hypothesised that they might be caused by an increase in global purchasing power or a decrease in the average price of music. Both of these hypotheses were quickly laid to rest. While global purchasing power has experienced significant variations, both up and down, during the timeframe, these variations were much smaller in amplitude and did not correlate with the decrease in music piracy over the same period. The average price of music has actually increased by a factor of 3 (Oxenford, 2009). We found the overall data, and a few high-variance subsamples, to confirm the relationship between music consumption and convenience.

We were able to obtain channel-segmented revenue data from 5 song writing artists whose music is available on Youtube, iTunes, Spotify, Soundcloud, Deezer, in stores, and through radio, TV and cinema deals, brokered by the relevant composer representative bodies in their respective countries. Not all 5 artists were present on all 6 channels. Based on these we were able to compute convenience scores as follows:

Table 1. Singer / Song Writer – Distribution channel convenience scores (Source: authors' own research, 2018)

Convenience Convenience							
Artist	YouTube	iTunes	Spotify	Sound Cloud	Deezer	In Store	Radio & TV
A1	289394	7388	167489	1239	2455	4638	
A2	288300		147723	2394			141244
A3	290001	8929	163992	1445	3499	12927	34099
R1	278002	3776	99212			281	673
R2	283734	8877					721

All the artists that took part in our research have music on YouTube, which makes sense as YouTube is by far the most convenient distribution platform, bringing the most revenues to artists showcasing their work. The convenience scores for YouTube were also the most homogeneous, which is probably explained by the YouTube monetization mechanism. Spotify comes in second in terms of convenience for the artists, with relatively homogeneous results for 3 of the 4 artists using it. The significant difference in the case of the fourth is probably due to geographical / market reasons. The three artists with higher convenience scores for Spotify are from the same country in Western Europe whereas the other two are from the same country in Eastern Europe. One artist had a very high convenience score for the Radio, TV, and Cinema distribution channel. This outlying result is due to the use of one of their songs in a motion picture.

A surprising discovery was that the convenience scores of iTunes were far inferior to those of YouTube and Spotify while being relatively homogeneous. In addition to that, based on information from the artists, we identified a link between the availability of an artist's music in stores and its availability on iTunes, where in store distribution appears to be a precondition of the music being listed on iTunes.

Sound Cloud and Deezer, although in the same "on demand" category as Spotify, are far less interesting in terms of convenience scores, most likely due to the platform's monetisation scheme. This shows in the more limited adoption of these platforms by artists, although another important take away from our results is that artists do not optimise their use of distribution channel based on objective criteria.

Conclusions

Wide-spread, fast internet connections and the latest developments in music streaming software have challenged the status quo within the processes of music creation and distribution. Streaming services such as Pandora or Spotify have adapted to the consumer's preferences, inventing a business model that is both sustainable, accessible and profitable. However, controversies and resistance did not hesitate to appear, bringing into the public eye the issue of funding the artist, an old problem that becomes more prominent when the revenue structure changes as a result of new human behaviour combined with innovative technologies.

A system that makes it appealing for individuals to buy access to an incredibly extensive song database makes it less effective to pirate copyrighted content. Convenience is key when it comes to reducing piracy to a minimum, but it is a mix of convenience for the customers and convenience for the artists themselves that pushes the business models and the industry in the right direction.

Abstract. *In the past decade the business field has encountered a shift towards knowledge economy and a change of principles in the direction of sustainability, wealth and innovation. Although the innovation level of a region overall is difficult to assess, indicators, such as patent applications or enterprises introducing an innovation with environmental benefits offer a measurement tool for this aspect. The present study estimates first a panel regression model with patent applications to the European patent office as dependent variable in connection to other economic and research and development factors between 2010-2014 for the selected European Union member states. The second part of the study focuses on a regression for 2014 having the enterprises that introduced an innovation with environmental benefits obtained within the enterprise as a dependent variable and economic independent variables also in the case of certain selected European Union countries. Therefore, the present paper inquires two types of dependent variables regarding innovation and proposes to offer dependencies models between innovation and economic indicators based on regression models. The results indicate a relationship with expenditures on research and development on regional level, as well as enterprises development for the selected countries of the European Union. While innovation is mostly treated as a separate independent factor in the economic system, a systematic approach of innovation is significant for it to be designed and created, in order to ensure the basis for further innovation stimulating policies. From a statistical point of view, a main current issue is represented by the selection of relevant indicators measuring innovation levels on a regional level, most indicators being more qualitative and subjective than quantitative. The relevance of the study lies in the fact that the subject is a novelty in terms of scientific literature, as these indicators have not been tested throughout other regression models before.*

Keywords: *innovation; research and development; patents, economy; environment*

Introduction

As the pressure towards knowledge economy and technology development increases, the issue of generating innovations in numerous sectors of activities has become. Generating innovation has become a main factor for the long-term efficiency and development of enterprises and organizations globally. If until two decades ago bringing small improvements to existing products or bringing new versions of products and services would have been competitive features of a company, today the need for essential innovations, especially in terms of sustainability, technology, organization and not only are imperatives in order to be able to maintain one's own position on the market and further grow.

Innovation and its measurement indicators have been studied by several authors and organizations, that have endeavored efforts in order to find optimal systems of indicating the innovation level, as well as the factors, that lead to innovative behavior. Innovation is frequently associated as a term with "invention" although the literature disputes often their use as synonyms, as innovation is considered by some as a new product or technology created using novelty and being marketable, or introduced into production, management and other activities, while invention refers to a progressive novelty new for the organizational systems (Manuylenko et al., 2015). Schumpeter (1982) was one of the first to define innovation as utilizing new combinations of existing productive forces to solve the problems of business (Kogabayev & Maziliauskas, 2017). According to OECD (2005) innovation means "the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations". Innovation has been linked to value creation for stakeholders as more authors mention (Špaček & Vacík, 2016; Kanten & Yaşlıoğlu, 2012; Hsu & Fang, 2009).

Currently one main strategic issue referring to innovation is represented by finding appropriate measurement indicators to determine the degree and efficiency of innovation on organizations, countries', regional level and factors, that could influence these innovation indicators. Three of the most frequently used indicators in measuring innovations are patents, patent citations and patent applications, however several other factors can be measurement units for the degree and efficiency of innovations (Information Resources Management Association, 2018).

The main objective of the present study was to estimate an OLS panel regression model, that reveals a connection of a main innovation indicator, namely patent applications to the European patent office by priority year to four independent variables: national public funding to transnationally coordinated research and development (R&D) in Million Euros, business expenditure on research and development (R&D) in Million Euros, job-to-job mobility for ages 25-34 years in thousands, high-tech patent applications to the European patent office by priority years (total number) for the period 2010-2013. Furthermore, further tests are performed in order to determine the most efficient model, including the Durbin-Wu-Hausman test. The joint test and the Wald test are further implemented. The second part of the practical analysis referred to another OLS regression model having enterprise innovation with environmental benefits as a dependent variable in connection to the independent variables: transnationally coordinated research and development (R&D) in Million Euros, business expenditure on

research and development (R&D) in Million Euros and high growth enterprises by 10% or more and related employment. The results of the study revealed that factors such as job-to-job mobility and national funding to transnationally coordinated research and development can have a significant impact on the indicators selected for innovation measurement.

Literature review

As a main key factor for economic growth innovation has become one of the main contemporary strategic issues of organizations, countries and regions globally. Simultaneously with the increased dynamics of competition and technology development, customer changing preferences and the development of innovative products on a high scale, the term of innovations itself has become a main strategic issue overall in the business field, as well as all the other sectors of activities, in order to maintain the possibility of expansion and development for the future. Several authors have inquired the subject of innovation and have provided several definitions.

The main definition of innovation was given however by Schumpeter (1982), who defined the term "innovation" as utilizing new combinations of existing productive forces to solve the problems of business as mentioned in the article of Kogabayev and Maziliauskas (2017). Other authors have confirmed practically in their studies this definition of innovation given by Schumpeter (1982). According to Cingula and Veselica (2010) innovation is the use of new knowledge to offer a new product or service that customers want and thus, not only the invention itself is essential in the case of innovations, but also their trading on the market. Brătianu (2011) defines the term innovation as "to create a new entity and to bring it in its final market form".

Regarding the types of innovation, Tanțău and Staiger (2018) mention the following main types:

- a) product innovation or introducing new, redesigned or essentially improved products or services;
- b) business model innovation, such as changes of the value proposition or other components of a business model, that ultimately create value for the organizations;
- c) process innovation, referring to incremental process improvements, that could have as main objectives, time or costs decrease, improved financing or coordination (Davenport, 1993);
- d) organizational innovations and marketing innovations, such as new marketing channels or new marketing concepts (Doyle and Bridgewater, 1998). Zawawi et al. (2016) describe another main type of classification of innovation as technological and administrative or managerial, as described in Figure 1, the combination of the two bringing significant contribution to the organization's competitiveness potential.

Figure 1. Dimensions and components of innovations
(Afuah, 1998; Yang, 2009; Zawawi et al., 2016)

In order to be successfully implemented and accepted by the public innovations have to be economically reasonable and thus, their practicability on a micro-level is a key factor in their introduction in a market economy as mentioned by Bock and Hasenkamp (2013). Referring to the general approach of the innovation process, Tohidi and Jabbari (2012) offer structure of this process, as illustrated in Figure 2:

Figure 2. The innovation process
(Source: Tohidi and Jabbari, 2012)

Dan et al. (2011) mention that innovation is linked to knowledge and may be described as "also described as a part of a management process that may need to draw on other organizational resources that creativity does not". A main issue regarding the innovation development is represented by the measurement of innovation. While many refer to innovations generated in several fields, the measurement of innovation and the selection of appropriate indicators for the measurement remains a challenge for the management of organizations, as well as on a regional level. The main general indicators, that measure development in terms of innovation are currently considered as: the

patents (or patent applications) and patent citations, described as indicators measuring the investments output into new knowledge and technology (Information Resources Management Association, 2018), new products or services and process innovations. Although patents and patent citations are considered main indicators for innovation other types of indicators are also accepted for measuring innovation development, such as number of trademarks, increased customer loyalty levels, awards and honors for innovations, inventions suggestions, disclosures as to measuring rates of ideas generation within organizations, research and development expenditure, high-technology exports, researchers in research and development activities (Phen, 2013; Maradana et al., 2017).

As more types of innovations are emerging in time also measurement indicators are expected to expand and diversify.

The interconnection of innovation to economy and economic growth has been researched by more authors and has been confirmed through numerous studies. For example, Ulku (2004) proved through a panel model for 20 OECD countries and 10 non OECD countries for the period between 1981-1997, that innovation has a positive effect on GDP per capita, while research and development expenditures increased the level of innovation. The strong connection between innovation and economic growth has also been confirmed by the study of Peece et al. (2015) for the case of Poland, Czech Republic and Hungary between 2000-2013 through estimation of a regression model. Maradana et al. (2017) emphasize the bidirectional system of innovation causing economic growth, as well as economic growth leading through more innovation creating a circle of development and growth regarding both factors.

The present paper offers another perspective of influencing factors on innovation through the ordinary least squares regression models and testing in order to emphasize new independent variables in connection with the selected innovation indicators.

Methodology

In order to perform the empirical analysis of the present study, we selected one dependent variable, namely patent applications to the European Patent Office (EPO) by priority year, as well as four independent variables: business expenditure on research and development (R&D) in Million Euros, national public funding to transnationally coordinated research and development (R&D), high-tech patent applications to the European Patent Office (EPO) by priority year, job-to-job mobility age (between 25-34 years old) in Thousand for the case of the following European Union countries: Belgium, Bulgaria, the Czech Republic, Denmark, Germany, Estonia, Greece, Spain, Croatia, Italy, Cyprus, Latvia, Lithuania, Hungary, Malta, the Netherlands, Austria, Poland, Portugal, Romania, Slovenia, Slovakia, Finland, Sweden, United Kingdom.

The patent applications to the European Patent Office refer to the requests for protection of an invention directed either directly to the European Patent Office (EPO) or filed under the Patent Cooperation Treaty and designating the EPO (Euro-PCT), while the indicators refer to the number of applications per country (Eurostat, 2018a). Business expenditure on research and development is expressed in million Euros.

National public funding to transnationally coordinated R&D (Mil. Euro) refers to the total budget financed by the government (state, federal, provincial), as measured by GBAORD directed to transnational public R&D performers and transnational public R&D programs according to Eurostat (2018b). High-tech patent applications to the EPO by priority year refer to patents in the high-tech sector. The term “patents” reflects a country's inventive activity, as well as the country's ability to exploit knowledge and transform this into economic gains as mentioned in Eurostat (2018c). Thus, patent statistics are broadly used to evaluate the inventive performance of regions. Contrary to general beliefs that patents generally refer to technology patents, the high-tech patents account for only a quarter of the total patents. For example, in 2012 high-technology patent applications to the European patent office accounted for approximately 23,9% of the patent applications made at the European patent office, while the rest of the patent applications were related to other fields (Eurostat, 2018d). Job-to-job mobility age (25-34 years old) in Thousand refers to the movement of individuals between one job and another from one year to the next (Eurostat, 2018e). Personnel fluctuation can have an impact on costs and innovation levels of the institutions and enterprises, as it can impact negatively the level of employee or team's creative initiatives and the overall level of innovative and financial progress of the organization.

The source of the statistics indicators is Eurostat, while we estimated a panel regression model for the analyzed period was 2010-2013. The Stata software was used for analysis of the econometric models described in the Findings and analysis section.

Based on the previously mentioned variables we first estimated a panel regression model, that determined the impact of the independent variables on the patent applications to the European patent office by priority year (PAE), namely:

$$PAE_{it} = \alpha_i + X_{it} \times \beta + \varepsilon_{it} \quad i = 1 \dots N, t = 1 \dots T$$

where X refers to the the explanatory variables, the i refers to the country and t refers to the year or the time series perspective.

Secondly, we performed the random effects and fixed effects OLS panel regressions and then we tested with the Durbin-Wu-Hausman test which of these was more efficient in our case. Furthermore, the joint test, Waldman test were performed, as well as an OLS panel regression with lagged variables, implying the effect of the independent variables in the previous year on the current year dependent variable.

Another inquired OLS regression was done for 2014 for another selection of variables, namely: the dependent variable, enterprise innovation with environmental benefits and three independent variables: national public funding to transnationally coordinated R&D (Mil. Euro), business expenditure on research and development (R&D) and high growth enterprises by 10% or more and related employment. This was performed for the European Union states with the available data for 2014 from Eurostat. The statistics available on Eurostat referred only to this year. This OLS regression analysis was done, as enterprises innovation with environmental benefits is another significant innovation measurement indicator and refers to enterprises that introduced an innovation with environmental benefits obtained within the enterprise (Eurostat, 2018f). High-growth enterprises by 10% or more and related employment refer to enterprises with a

turnover growth of over 10% and related employment as the growth is measured by turnover or number of employees (Eurostat, 2018g).

The present research offers a new approach on innovation, as previous studies have not inquired the relationship of these variables on this main indicator of measurement for innovation.

Findings and analysis

Innovation is a broad concept, that has always represented a challenge for measuring in the sense of its development and effects on different levels, such as on company level, regional, national, international level. Roos and O'Connor (2015, p.67) mention the recommendation of using multiple indicators to measure efficiently innovation, such as research and development expenditure, patent counts and citations, new products and other variables. For the panel regression model we have selected as mentioned in the Methodology a dependent variable for measuring innovation the patent applications to the European patent office by priority year, while the independent variables were: national public funding to transnationally coordinated research and development (R&D) in Million Euros, business expenditure on research and development (R&D) in Million Euros, job-to-job mobility for ages 25-34 years in thousands, high-tech patent applications to the European patent office by priority years (total number) for the period 2010-2013. The selected 25 countries from the European Union, for which data could be found on Eurostat (2018h).

Table 1. Ordinary least squares (OLS) panel regression with random effects 2010-2013 European Union (Authors' own research based on Eurostat data (2018h))

Dependent variable: Patent applications to the EPO by priority year (PAE)	Coef.	St.Err	t-value	p-value	Sig.
Independent variables: Business expenditure RD (Mil. Euro)	0.1835	0.0338	5.43	0.000	***
National public funding to transnationally coordinated R&D (Mil. Euro)	2.7196	1.5110	1.80	0.072	*
High-tech patent applications to the EPO by priority year	3.2067	0.2697	11.89	0.000	***
Job-to-job mobility age (25-34 years old) in Thousand	-5.1284	2.1210	-2.42	0.016	**
_cons	43.5568	240.1721	0.18	0.856	
Mean dependent var	1909.3900		SD dependent var		4467.1500
Overall r-squared	0.9782		Number of obs		100
Chi-square	405.2631		Prob > chi2		0.0000
*** p<0.01, ** p<0.05, * p<0.1					

The results of the performed econometric analysis indicated that job-to-job mobility by age in the sector 25-34 years represents a significant determinant of patent application

to the European patent office as shown in Table 1: an increase of 1000 in job-to-job mobility (25-34 years) will involve a decrease of the patent applications to the European patent office by 5.12, when all other variables are constant, so this factor will impact indirectly proportionally the inquired dependent variable. The job-to-job mobility, implying the mobility of individuals from one job to another from one year to the next (Eurostat, 2018e) is a demotivating factor for innovation, as it implies costs, losses and less long-term involvement of employees in innovative processes within organizations.

High-tech patent applications to the European patent office also seemed to be influencing significantly and positively the patent applications to the European patent office (EPO) by priority year, namely an increase of one in the number of high-tech patent applications will lead to an increase of approximately 3.2 patent applications to the European patent office by priority year. This could be explained by the high-tech innovations, as having an important impact in the innovation levels overall. The other independent variables also involve an increase of the dependent variable, namely a 0.18 increase in patent applications at the European patent office at an increase of 1 million Euros of the business expenditure on research and development and a 2.71 increase of the dependent variable at an increase of 1 million Euros of national public funding to transnationally coordinated R&D.

The four selected independent variables explain in the amount of 97% the dependent variable of patent applications to the European patent office by priority year, as the overall R-squared is 0.97. We assume that country-specific effects are not correlated with the independent variables.

Furthermore, we estimated the fixed effects for the OLS panel regression for 2010-2013 for the same selection of European Union countries. We test for the effects which are not dependent on time, but on the country itself. The omitted variable bias is caused due to the country-specific effects with the independent variables. These country-specific effects are hidden. We estimate the fixed-effects in order to correct for the omitted variable bias. The OLS assumptions (constant variance) make it compulsory that the errors for each entity or country in our case are not correlated over time. This will be tested at a later point through the modified Wald test. The coefficients found in the fixed-effects differ because the effect for each country on the dependent variable has been removed from the coefficients and practically it is the same as adding an equivalent dummy variable for each country.

Table 2. OLS panel regression with fixed effects 2010-2013 for the European Union (Source: Authors' own calculations based on Eurostat data (2018h))

Patent applications to the EPO by priority year	Coef.	St.Err	t-value	p-value	Sig.
Business expenditure RD (Mil. Euro)	-0.1271	0.0305	-4.17	0.000	***
National public funding to transnationally coordinated R&D (Mil. Euro)	1.2374	1.0228	1.21	0.230	
High-tech patent applications to the EPO by priority year	1.0313	0.2219	4.65	0.000	***

Job-to-job mobility age (25-34 years old) in Thousand	0.0207	1.8030	0.01	0.991	
_cons	2117.0466	170.9396	12.38	0.000	***
Mean dependent var	1909.3900		SD dependent var		4467.1500
R-squared	0.5663		Number of obs		100
F-test	23.1802		Prob > F		0.0000
Akaike crit. (AIC)	1240.6891		Bayesian crit. (BIC)		1253.7149
*** p<0.01. ** p<0.05. * p<0.1					

In order to test which of the fixed-effects or random effects models will lead to a more relevant result we apply a Durbin-Wu-Hausmann test, where the null hypothesis is that the preferred model is the random effects versus the alternative fixed effects. In our case, as Prob>chi2=0.000, thus being below 0.05, we reject the null hypothesis that the unique errors are uncorrelated with the variables and thus, this is an indication that there is a strong fixed effects model.

Table 3. Durbin-Wu-Hausman test (Source: Authors' own calculations based on Eurostat data (2018h))

Patent applications to the EPO by priority year	Coefficients (b) Fixed	Coefficients (B) Random	(b-B) Difference	Sqrt(diag(V_b-V_B)) S.E.
Business expenditure R&D (Mil. Euro)	-0.1270818	0.1835434	-0.310625	0.0416872
National public funding to transnationally coordinated R&D (Mil. Euro)	1.237351	2.7196	-1.482249	0.9810698
High-tech patent applications to the EPO by priority year	1.031279	3.206712	-2.175433	0.2829068
Job-to-job mobility age (25-34 years old) in Thousand _cons	0.0206619	-5.128436	5.149098	2.363735

Whether time fixed effects have to be added we can test with a joint F test if the dummies for all years are jointly zero. The result of the F-test let us conclude that time fixed effects do not have to be included. Prob>F < 0.05 to reject the null hypothesis that time fixed effects should be included.

Table 4. JOINT TEST (Source: Authors' own calculations based on Eurostat data 2018h))

F test that all $u_i=0$; F(24, 68)=93.05 Prob>F=0.0000
Testparm _lyear* (1) _lyear_2011=0 (2) _lyear_2012=0

(3) _lyear_2013=0
 F(3,68)= 4.35 Prob>F=0.0073

Finally, we perform a modified-Wald-test for panel data sets to test whether the errors have constant variance (homoscedasticity) which is a basic assumption of OLS holds for the fixed effects model. The null hypothesis can be rejected and to obtain efficient estimators an OLS panel regression with robust standard (also known as Huber White estimators) have to be estimated. The null hypothesis is $\sigma(i)^2 = \sigma^2$ for all i . Sigma denotes the variance. Applying a χ^2 distribution the test statistic is $4.7e+07$, while the $\text{prob} > \chi^2 = 0.000$. The null hypothesis can be rejected by a 5% significance level.

Table 5 presents results of the OLS panel regression with robust standard errors. The variables Business Expenditure R&D and the number of high tech patents are significantly associated with the total number of patent applications respectively negatively and positively.

Table 5. OLS panel regression with fixed effects with robust standard error 2010-2013 for the European Union (Source: Authors' own calculations based on Eurostat data (2018))

Table 6 illustrates the results of the OLS panel regression with lagged variables. Model 1 estimates a current dependent variable, patent applications to the EPO by priority year in connection to the selected independent variables from the current year as well, namely independent variables business expenditure, national public funding to transnationally coordinated R&D, high-tech patents and job-to-job mobility.

Model 2 implies, that the job-to-job mobility from a previous year is positively associated with the amounts of patent application to the EPO by priority year in the current year. For example, in model 1 the regression model refers to patent applications to the EPO of 2012 for the European Union countries with independent variables business expenditure, national public funding to transnationally coordinated R&D, high-tech patents and job-to-job mobility in 2011 and the same principle applies for the other years taken into consideration for the study. The amount of high-tech patents in the previous year is significantly associated with patent applications to the EPO in the current year.

Model 3 is the estimation of the current value of the dependent variable patent applications to the EPO by priority year to the selected independent variables from two years ago. The results are that the job-to-job mobility from two years ago is positively associated with the amounts of patent applications to the EPO in the current year. Because coefficients of model 3 are lower, this means the effect of the independent variables of two years ago is less strong on the dependent variable from the current year than the effect of the independent variables one year ago on the dependent variable from the current year. Estimations are controlled for fixed effects and robust standard errors are applied.

Table 7. Ordinary least squares (OLS) regression for the period 2014 in the European Union (Source: Authors' own calculations based on Eurostat data (2018h))

Dependant variable	Coefficients	Std. Error	t	p> t	
Enterprise innovation with environmental benefits					
Independent variables					
National public funding to transnationally coordinated R&D (Mil. Euro)	19.06258	4.836198	3.94	0.001	No of observations=24 F (3,20)=253.46 R squared=0.9744 Prob>F=0.0000 Adj. R squared=0.9705
Business expenditure on R&D (Mil. Euro)	0.490576	0.0769413	6.38	0.000	
High growth enterprises by 10% or more and related employment	0.3693516	0.2117083	1.74	0.096	

For 2014 we also estimated a regression for enterprise innovation with environmental benefits as a dependent variable in connection to three independent variables: national public funding to transnationally coordinated research and development (R&D), business expenditure on research and development (R&D) and high growth enterprises by 10% or more and related employment, as shown in Table 7. The variable enterprise innovation with environmental benefits refers specifically to enterprises that introduced an innovation with environmental benefits obtained within the enterprise. We estimated the regression for 24 countries of the European Union, as for the rest this data was not available on Eurostat. The selected countries were: Bulgaria, the Czech Republic, Denmark, Germany, Estonia, Greece, Spain, Croatia, Italy, Cyprus, Latvia, Lithuania, Luxembourg, Hungary, Malta, Austria, Poland, Portugal, Romania, Slovenia, Slovakia, Finland, Sweden, Serbia.

As one can observe in the table above the highest coefficient had a value of 19.06258, meaning that an increase of 1 Million Euro of national public funding to transnationally coordinated research and development can number of enterprises that introduced an innovation with environmental increase the benefits obtained within the enterprise by 19,06. This emphasizes the importance of funding to transnationally coordinated research and development programs for the increase of the number of innovations, as well as for stimulating enterprises to act in the sense of innovation.

The second coefficient of 0.490576 means that an increase of business expenditure on research and development of 1 Million Euro can lead to an increase of 0.49 in the number of enterprises that introduced an innovation with environmental benefits obtained within the enterprise, while an increase of one unit of High growth enterprises by 10% or more and related employment can lead to an increase of 0.3693516 in the number of enterprises that introduced an innovation with environmental benefits obtained within

the enterprise. As the adjusted R-squared is 0.97 it means that these three independent variables explain in proportion of 97% the dependent variable. It implies the regression model has a strong explanatory meaning.

Conclusions

As a conclusion a main result of the study is that the job-to-job mobility by age in the sector 25-34 years is a significant determinant of patent application to the European patent office for the selected period 2010-2013 in the sense of a higher job-to-job mobility decreasing patent applications, as less effort and time is invested within an organization contributes to demotivating innovation levels. Secondly, national public funding to transnationally coordinated R&D (Mil. Euro) can contribute to increasing the number of enterprises that introduced an innovation with environmental increase the benefits obtained within the enterprise as mentioned in the case of the regression model for 2014 having enterprise innovation with environmental benefits as a dependent variable.

Innovation is a challenge nowadays for organizations worldwide, involving tremendous efforts from the side of the employees, as well as employers and for funding programs. While the expenditures in the research and development initiatives and the longer periods spent within organizations seem to positively influence the innovations in the sense of patent applications to the European patent office, emerging factors connected to market dynamics and technology development are expected to bring new indicators influencing innovation levels. A main future objective of research is to analyze patent applications and enterprise innovations with environmental benefits in connection to new external factors, that will be imposed by future economic and technological developments in the coming years.

Abstract. *This paper aims to analyze the level of financial integration for the new member states of the European Union from Central and Eastern Europe: Romania, Poland, Hungary and the Czech Republic. There was implemented an analysis of sigma-convergence and beta-convergence for different economic periods (recession or economic growth). The results were in line with the initial expectations. It has come to the conclusion that the level of financial integration for the capital markets of these countries increases in good economic times and decreases in times of crisis when the volatility in equity markets increases. It was also observed that Romania was the country that recorded the most important progress, both in terms of sigma-convergence (which captures the reduction of discrepancies) and in terms of beta-convergence (speed of convergence). Also, the past few years have come together with the highest level of integration in capital markets in CEE countries, mainly due to the strong recovery after the recession from 2008, but also due to the improvements that each country has made in the field of correlating its business cycle with Euro Zone. Further, the methodology can be extended in order to cover the forex market, the money market or the bond market.*

Keywords: *equity markets; integration; volatility; convergence; economic downturn; time-series.*

Introduction

The financial integration of the countries that have recently joined the European Union is a hot topic and an extremely difficult issue to quantify. It is widely accepted that financial integration should be analyzed in different market conditions at different times, because the behavior of financial market is different during times of crisis compared to normal market situations. The level of financial integration is decisive for the accession of these countries to the Eurozone, but also for the health of the Eurozone and for how the business cycles of these countries are correlated. At the same time, a strong correlation also brings disadvantages such as the more rapid transmission of negative shocks and, implicitly, of economic crises to all member countries.

This paper will analyze the level of financial integration for the countries from the Central and Eastern Europe (Romania, Poland, Hungary and the Czech Republic) taking into consideration the evolution of their capital markets. Thus, the level of convergence (sigma-convergence and beta-convergence) of the capital markets in these countries relative to the Eurozone will be analyzed. This paper will try to highlight some

differences between countries in terms of integration level, but also to highlight the time differences of the integration level. The analysis was carried out over 3 different periods: pre-crisis (2000-2006), crisis period (2007-2011), post-crisis period (2012-2018).

The novelty of this research is represented by the inclusion of Romania in the study, which is one of the newest members of the European Union. Another novelty element is represented by the division of the analyzed period into 3 sub-intervals in order to capture the evolution of the convergence in three different markets: exuberance before the crisis, panic during the crisis, and post-crisis caution. Having this division and applying the classical methodology revealed by the scientific literature, we expect to obtain results relevant to the desired approach. Thus, we expect the level of integration to decline in the period of crisis and to improve later, as volatility and market panic decrease. At the same time, we expect to have a higher level of convergence in the post-crisis period, given the fact that most of the countries considered for the analysis will be members of the E.U. for at least 10 years, and the integration should have been achieved to a large extent.

Taking all of these expectations and hypotheses into consideration, we will go further towards the study. In the end, we will try to identify ways to extend idea in a future research. At the same time, it is very important to recall the importance of this research and the importance of this current contextual theme in the European Union, having in mind all the talks on reforming the union. All these debates will pose a challenge for the integration of financial markets, leading to mistrust among investors, which could finally lead us to a decrease in convergence in the coming periods, accompanied by an increase in market volatility.

Literature review

Financial integration at the E.U. level has been an important and constantly debated issue in recent years in the relevant literature. At the same time, such a theme was the starting point for many papers published by the EC's economists, balancing both the costs and the benefits of higher financial integration. Such works could be based on Baele et al. (2004) or Agenor (2003) publications, which introduce quantitative concepts and qualitative measures to capture the level of integration and convergence such as price-based measures, quantity-based measures or news-based measures.

The level of financial integration can be studied together with another problem: contagion in the financial markets. In this regard, we can mention the researches of Egert and Koubaa (2004), through which financial market contagion is studied using GARCH (conditional heteroscedasticity) models. Syllignakis and Kouretas (2006), or Egert and Kocenda (2005), may also be reminded, as they focus more on the phenomenon of cointegration in the financial markets. They also brought attention to the usefulness of applying the Granger test for causality on the Polish capital market to highlight how it reacts to a shock on another market.

An extremely important previous work for our paper is that published by Babetskii, Komarek and Komarkova (2007), which addresses the issue of financial integration in the countries of the Central and Eastern Europe. This paper addresses the two well-known convergence theories from the relevant literature: beta-convergence and sigma-convergence. The analysis is very useful, because it was detailed and expanded at the

level of the economic sectors which are represented on the stock exchanges. Also, the same topic was analyzed by Babecky, Komarek and Komarkova (2013). They made a more recent research regarding the level of integration based on the sigma-convergence and beta-convergence, but this time they expanded it to other financial markets, alongside the capital market: the forex market, the money market and the bond market. Considering all these facts, they have been able to raise an important topic and have been able to draw a series of relevant conclusions regarding the level of financial integration in the countries from the Central and Eastern Europe.

The experience of the most recent economic and financial crisis has proven to us that markets can be atypical at times of tension and thus the level of integration may vary from time to time, depending on the overall economic situation. Therefore, the level of integration and stability of markets may be dependent on the economic situation, but there is a possibility that the situation may be in the opposite direction. We can also talk about a dependence of the economic conditions on the situation on the financial markets, on the stability of the financial markets. A paper addressing this issue is that of Mendoza et al. (2009), but the literature is rather poorly developed in this direction. Therefore, the present research will also highlight the variation in time of the level of integration and stability of the financial markets depending on the economic period, depending on the economic evolution.

The research will be continued by studying beta-convergence and sigma-convergence in accordance with the methodology proposed by Adam et al. (2002) and later extended by Babetskii, Komarek and Komarkova (2007) and Babecky, Komarek and Komarkova (2013). This methodology will be applied to countries from the Central and Eastern Europe (Romania, Hungary, Poland and the Czech Republic). Also, we will take into account the research of Mendoza et al. (2009) regarding the time variation of the level of integration and stability of the financial markets according to the economic conditions and we will try to emphasize how the financial integration can change over time depending on the economic conditions.

Methodology

Financial integration can be analyzed using two methods, based on the law of one price: a) price-based measures and b) news-based methods, but this paper focuses only on the first method. It may be extended in the future to take into account the news-based methods.

We are going to apply price-based methods in accordance with Adam et al. (2002) and Babecky et al. (2013), who described and used the concepts of sigma-convergence and beta-convergence applied for the financial markets, which is the case for this paper. Beta-convergence shows us the speed at which the differences between indices' returns are eliminated. A negative value for the beta coefficient reveals that the convergence is taking place. This coefficient has to be as close as possible to -1. The closer to -1, the higher is the speed of convergence.

The second concept is the sigma-convergence which reveals the dispersion between the yields of some asset classes or some instruments (in this case stock markets indices). The sigma-convergence takes place when the coefficient falls to zero. Hence, the value of sigma has to be as close as possible to 0.

In order to calculate daily returns we are going to use the following formula:

$$r_t = \ln\left(\frac{S_t}{S_{t-1}}\right)$$

Where r_t - is the return at moment "t", S_t - is the price of the index at moment "t" and S_{t-1} - is the price of the index at moment "t-1"

Based on these notation, we can use the following formula for quantifying beta-convergence as Babecky et al. (2013) did:

$$\Delta R_{i,t} = \alpha_i + \beta R_{i,t-1} + \sum_{l=1}^L \gamma_l \Delta R_{i,t-l} + \varepsilon_{i,t}$$

Where $R_{i,t} = r_{i,t} - r_t^B$ is a difference between the return for an index for a specific country "i" and the return for the benchmark index for the Euro Zone, all of them at time "t". L is the maximum number of lags taken into consideration for the analysis. In this paper we are going to use L=3. The last term, $\varepsilon_{i,t}$ is a white noise, an error term which is normally distributed with mean zero and variance 1.

The above regression is going to be estimated a few times for each country, for different sub-intervals, in order to get relevant values for the beta coefficient. As stated above, a negative beta coefficient reveals that the convergence occurs. The closer the value for this coefficient is to -1, the higher the speed the convergence.

Further, we need to present the methodology for sigma-convergence. Hence, we are going to use the following formula, as it was stated in a lot of scientific articles:

$$\sigma_t = \sqrt{\frac{1}{N} \sum_{i=1}^N (r_{i,t} - \bar{r}_t)^2}$$

Where $\bar{r}_t$ is the average return over time and N represents the number of countries taken into consideration for the sigma-convergence approach. For this paper, we are going to use N=2 in order to analyze the sigma-convergence over time for each country related to the Euro Zone (Euro Stoxx 50). As it was stated at the beginning of this chapter, the sigma-convergence appears when the value for this coefficient is getting closer to zero. Also, it has to be noted that it takes only positive values.

The paper will present the evolution of the sigma convergence for the 4 countries compared to the Euro zone, for three different time periods:

- 13/12/1999 - 31/12/2006 - the period before the economic and financial crisis;
- 01/01/2007 - 31/12/2011 - the period of the economic crisis and the sovereign debt crisis in the Euro Zone;
- 01/01/2012 - 20/09/2018 - the post-crisis period - the period of economic growth and stability in the financial markets.

For a more appropriate graphical illustration and in order to better capture the trend in financial integration from each sub-interval, we are going to use the Hodrick-Prescott filter with a smoothing parameter: $\lambda = 270,400$, as it was recommended by Babetskii et al. (2007) and as Babecky et al (2013) did.

The data

There have been used daily observations for the equity market indices for each country from the Central and Eastern Europe (Romania, Poland, Hungary and the Czech Republic) and the Eurozone.

Euro Zone: Euro Stoxx 50

Romania: BET index

Czech Republic: PX Index

Hungary: BUX Index

Poland: WIG20

Period: 10/12/1999 - 20/09/2018

Data for the equity market indices were processed in order to obtain daily returns, which were then used in identifying the two types of convergence: sigma and beta.

For a better knowledge of the datasets used, we are going to present further a few charts for the evolution of the equity market indices:

Figure 1. Evolution of the selected equity market indices: Euro Stoxx 50, Bet Index, WIG20 Index, BUX Index and PX Index
(Authors' own computation based on yahoo finance data)

Similar developments can be observed using these graphs, but also periods of divergence between the markets considered. A common and very easy to observe is the

impact of the 2008 economic and financial crisis on all capital markets, with a strong correction for each of the five equity indices. However, a simple comparative analysis of the evolution of the five indices cannot provide us with much information about the convergence of the capital markets in these countries. In order to deepen the discussion, it is necessary to move on to the analysis of daily returns to see how large the movements in these markets were in the chosen period of time.

Further, we'll look at the daily returns for the 5 indices. It can be noticed that there were two very high volatility periods: between 2001-2002 (dot.com crisis) and 2007-2008 (global economic crisis). During these periods there were daily returns ranging between -10% and 10% for 4 out of 5 indices. The BET index of the Romanian stock exchange registered the highest daily fluctuations ranging from -20% to 20% in the period 2001-2002. On the other hand, Poland's WIG20 stock index recorded the slightest fluctuations, with daily yields ranging from -8% to 8% for the entire period under review.

Figure 2. Daily returns of the selected five equity indices: Euro Stoxx 50, Bet Index, WIG20 Index, BUX Index and PX Index
(Authors' own computation based on yahoo finance data)

Results

First of all, we will present the evolution of coefficients for sigma convergence for each of the sub-interval for the analysis: (i) the period before the crisis, (ii) the crisis period (economic and sovereign debt crisis in Europe), and (iii) the post-crisis period in Europe. For a better illustration of the sigma coefficient trend in these periods it was used the Hodrick-Prescot filter with a smoothing parameter $\lambda = 270,400$, as specified in

the methodology chapter. We recall that the result of the analysis should be as close as possible to zero in order to achieve the sigma convergence.

Before global economic crisis – 13/12/1999 – 31/12/2006

***Figure 3. Evolution of the sigma coefficients for Romania, Poland, Hungary and Czech Republic in the pre-crisis period
(Authors' own computation based on yahoo finance data)***

The results obtained show that in the period before crisis, but also in the period prior to the accession of these countries to the European Union, the level of integration measured by the sigma convergence was quite low, and the turmoil periods on the financial markets have reduced this convergence. This can be noticed by the significant increase of the coefficient in 2001-2002 (dot.com bubble on the equity markets). Subsequently, as the economic situation has improved and some of the countries have joined the European Union, the level of convergence has improved significantly. During this first period it can be noticed that Romania is the country that made most of the times the discordant note against the others, being the only one that had not yet joined the European Union.

Therefore, during this period, we noticed a dependence of the level of convergence and financial integration on the economic conditions, but also on the membership in the E.U. Romania was the most decorrelated country, being the only one that was not a member of U.E. in the analyzed period.

Global financial crisis period and sovereign debt crisis in Europe (01/01/2008 – 31/12/2011)

***Figure 4. Evolution of the sigma coefficients for Romania, Poland, Hungary and Czech Republic in the crisis period
(Authors' own computation based on yahoo finance data)***

As a result of the estimates for the second sub-interval (the crisis period), it was again confirmed that in times of turmoil on capital markets the level of integration decreases, reaching a minimum of convergence for all four CEE countries at the end of 2008. It can also be noticed that Romania registered again the biggest divergence from the Euro Zone equity market. As the effects of the economic and financial crisis dissipated, we saw an increase in the degree of convergence gradually towards the end of the period. On the other hand, a new downturn in integration has emerged in 2011 as the sovereign debt crisis erupted, which has again brought tension and nervousness to the financial markets.

Post-crisis period (01/01/2012 – 20/09/2018)

The last analyzed period was represented by the last 6 years, a period characterized by sustained economic growth in the countries of Europe and especially in the countries of Central and Eastern Europe. Thus, we have had a period of low tension on the financial markets, a period of low volatility, which has helped the equity markets from Romania, Poland, Hungary and Czech Republic to increase the degree of convergence with the Eurozone.

Figure 5. Evolution of the sigma coefficients for Romania, Poland, Hungary and Czech Republic in the post-crisis period
(Authors’ own computation based on yahoo finance data)

Initial expectations that the level of integration of financial markets in the Central and Eastern European countries is growing during periods of economic growth is also confirmed by this last figure. Thus, at the end of 2017 was recorded the lowest value for the sigma convergence coefficient over the entire analyzed period and we can say that the financial integration for these markets has increased significantly. Consequently, the sigma- convergence has been achieved to a good extent. Furthermore, it is worth noting that a significant improvement has been registered by Romania. For the case of this country there was registered the lowest value for sigma convergence in this last period, highlighting the most integrated and correlated equity market with the Euro Zone capital market in this period.

Further, the results obtained after studying the beta-convergence for the same sub-intervals are presented using the below table (Table 1):

Table 1. Beta Coefficient - speed of convergence
(Authors’ own computation based on yahoo finance data)

Equity Market			
	Sep 1999 - Dec 2006	Jan 2007 - Dec 2011	Jan 2012 - Sep 2018
RO	-0.71	-0.64	-0.84
HU	-0.82	-0.87	-0.88
PL	-0.87	-0.81	-0.86
CZ	-0.83	-0.76	-0.82

We recall that the beta coefficient must be negative and close to -1. It shows the speed at which the convergence is achieved for each of the four countries relative to the Eurozone (benchmark).

Based on the above results, we can see that for 3 out of 4 countries the convergence rate decreased during the crisis period compared to the pre-crisis period, so that it would return to similar or better levels later. The best performance in terms of increasing convergence rate was registered by Romania, where the beta convergence coefficient has improved from -0.71 to -0.84, being much closer to -1. Improvements have also been registered by Hungary, while Poland and the Czech Republic have returned to the beta levels similar to those prior to the post-crisis period.

Conclusions

This paper aims to highlight the way in which the level of financial integration in the Central and Eastern European countries relative to the Eurozone is changing. Thus, it was analyzed the evolution of integration level in three different periods on the capital markets of these countries: the pre-crisis period (2000-2006), the crisis period (2007-2011) and the post-crisis period (2012-2018). For these periods, two concepts were studied to quantify the integration level: sigma- convergence and beta-convergence.

Following the analysis performed using the sigma-convergence coefficient, a number of facts were observed:

- the level of convergence sharply decreases in times of crisis in times of stress on financial markets and in times of economic stability this level is improving;
- in the period before the crisis and during the crisis period, the lowest level of convergence was registered for the case of Romania;
- on the other hand, in the period prior to the crisis, Romania recorded the best level of sigma convergence, signaling a significant progress towards the pre-accession countries. and the crisis period.

Following the analysis of beta-convergence using the beta coefficient, we obtained a series of conclusions that lead us in the same direction:

- in times of crisis and tensions in the markets, the level of convergence is decreasing, so that it can improve as the economic situation stabilizes;
- the speed at which the convergence was recorded in Romania during the pre-crisis period and during the economic crisis was the lowest of the analyzed countries. Subsequently, in the post-crisis period, the situation improved significantly for Romania, registering the greatest improvement.

In conclusion, we have succeeded in highlighting that in recent years, in the post-crisis period, a large convergence has been achieved for the equity markets from Central and Eastern European countries. However, we cannot say that it is sufficient for financial market convergence. In order to complete the study and to get significant conclusions about the level of integration of the financial markets in these countries, it is necessary to expand this research in the future. Thus, a similar analysis is needed for the money market, the bond market or the foreign exchange market in these countries. Considering these three markets and the equity market, a deeper conclusion could be reached regarding the level of integration of the financial markets in these countries relative to the Eurozone and the EU.
